And how high can it record speed? I'd like to try and nail a few
pimple-faced, pill-popping, high school dropouts who thinks 25MPH
speed limit means it's OK to rip down the road at 75. If it's
accurate enough, a video camera recording the speed and the offending
vehicle with its license place would stop them hopefully before they
get a new hood ornament in the form of a 3 year old child.

Very easy to build a gunn diode oscillator and scare the pants off
leadfoot at a 5+ mile range.

You need a gunn diode, 8 volt regulated supply, one small bypass cap
and copper end cap pipe fitting and piece of copper/ and some brass
screws to make a mount for the diode.

If you have an old radar detector with good gunn oscillator it can
also make a good X band source for triggering radar detectors - just
isolate the diode/horn sub assembly (you don't need the other parts
just the gunn diode, cavity, bypass cap and power supply). Tune the
cavity screws for maximum effect.

A video camera with on screen timer and known distance markers could
do the same thing - poor man's Vascar system . . .

Then you'd only have to fight the bureaucracy to make a citizens
arrest stick . . . or just convince the local TV station to take up
your cause - that would probably be a lot easier than dealing directly
with government.

Nope, it does "real speed" the amazon review says;

Amazon.com Review
Ever wonder just how fast you get your favorite Hot Wheels car to go? Or how speedy you are on your own bike? You donï¿½t need to be pulled over by a cop to find out. The Hot Wheels Radar Gun does the job for you, using all sorts of state-of-the-art technology. Just set the scale to 1/64th or real speed, and MPH or KPH, aim the gun at objects coming toward you or moving away, squeeze the trigger, and check out the digital readout. Simple as that! Now you can set new speed goals, and actually find out if youï¿½ve attained them. The 1/64th scale speed reflects the fact that Hot Wheels cars are 1/64th the size of a real car. So if a Hot Wheels car goes 10 MPH, the calculation is 10 MPH X 64 = 640 MPH! Now we begin to understand why those wheels are so hot! Requires four "AAA" batteries (not included).--Emilie Coulter

Product Description
Now you can read the speed of your favorite Hot Wheels racing vehicles. With point-and-read real-life styling and super-cool graphics. Not for use with some Hot Wheels vehicles. Requires 4 AAA batteries- not included.

I suspect its readout is scaled to Hotwheels scale, not
actual speed.

More important is that Extras at least should have to prove they can
solder, troubleshoot, and use test equipment do determine if a radio
operator is or is not in compliance.

I couldn't resist. :-)

Exactly how does one use solder to determine if a radio operator is or
is not in compliance?

Made my day.

On the box it claims it does actual speeds up to 100 MPH. It's a hot item on
EBAY, but you can get it cheaper at Walmart or Amazon, the sell it on ebay! ;)

There is this thing called a comma. We have three things here:

1. Solder.
2. Troubleshoot.
3. Use test equipment to determine if a radio operator is, or is not,
in compliance.

Three separate activities.

its a toy - doesn't say up to what speed it can read!

Features & Specifications

Now you can read the speed of your favorite Hot Wheels racing vehicles
with this Hot Wheels Radar Gun. With point-and-read real-life styling, and a
sharp, streamlined design, you'll prove once and for all who's king of the
road.

a.. Sleek red and silver design
b.. Cool graphics
c.. Simple point-and-read real life styling
d.. Not for use with some Hot Wheels vehicles
e.. Uses 4 AAA batteries, not included

> Jerry
>
Hi Sam,

FYI, the quadrifilar helix comprises two bifilar helices fed in phase quadrature. The result is hemispherical radiation in the radiation sphere. But the hemispherical radiation results from the combined radiations from each bifilar helix. Consequently, radiation from a single bifilar helix is spherical, with the polizarization sense the same throughout the sphere, unlike the radiation from a turnstile, which radiates one polarization sense above the equator and the opposite sense below the equator, where the turnstile elements lie on the equator.

You can find info on the bifilar helix in Chapter 22 of Reflections, eds 1 and 2. If you don't have a copy of Reflections available, Chapter 22 is available for downloading from my web page at www.w2du.com. Click on "Read Chapters from Reflections 2" and then click on 'Chapter 22, Quadrifilar Antenna'.

Fig 22-5 shows the radiation pattern for the quadrifilar, but the radiation in the 180ï¿½ direction is suppressed due to the effect of the second helix positioned 90ï¿½ from the first helix, and fed in quadrature (90ï¿½) relative to the first. In the absence of the second helix the radiation from a single bifilar is spherical.

Fig 22-8 shows a simple method of feeding the bifilar helix--it's called an 'infinite balun', because the current that would flow on the outside surface of

the coax when feeding a doublet dipole without a balun is now flowing on the outside surface of the radiator, which is what we want.

If you're interested in further info on the helices used in quadrifilars or bifilars, see the report on my R&D experiment on quadrifilars, in which I measured radiation patterns and driving point impedances on more than a thousand different configurations of the quadrifilar. The R&D report is available for downloading on my web page. Click first on "Read Appendices from Reflections 2", and then click on 'Appendix 13, RCA R&D Quadrifilar Helix Antenna'.

Hope this helps,

Walt Maxwell, W2DU

Ah, but English is a wonderful and bizarre language. The beauty of the
sentence is that it can, indeed (ESPECIALLY with the commas) be read the way
Bill brought up.

Cecil, I don't think there is a single answer to either of the
questions, if there is, it probably depends on so many assumptions as
to be even less relevant than the answer to those questions for a
dipole without the traps.

To illustrate the point, I have seen an optimal length / diameter
ratio proposed for the traps, but none of the articles that I have
seen explains what factors were considered in the optimisation, or the
extent of the optimisation. So what does an "optimised trap" mean?

My experience with coaxtraps on low HF is that they are relatively low
L/C and do not result in much shortening of the antenna. If one of the
reasons for trapping an antenna is to reduce its length, then other
trap designs are probably better for that purpose.

Interesting. Someone must be out there flogging a set of components
for radar guns. I bought a Bushnell one for measuring baseball speed
for < $100 not too long ago. It seems to agree fairly well (within a
couple MPH) with the professional models.

Best regards,
Spehro Pefhany

------------ REPLY FOLLOWS ------------

The way you have it written conjoins all three activities into one,
which is applied to determining if the radio operator, etc, etc.

Here's a better way:

"More important is that Extras at least should have to prove they can
solder, troubleshoot, and in addition, use test equipment do determine
if a radio operator is or is not in compliance.

There are some other styles that could be used too, but just stinging
together words separated by commas is begging for misinterpretation.
Perhaps you were absent that day.

"Unambiguous" is one of my favorite words. :-)

That is correct! It uses a 10.525GHz DRO circuitry.
Someone took it apart and posted the photos on the web.

Hmmm... since it is the same as x-band, I wonder if I used those on
freeway, maybe I could scare a few lead foots who has radar detector?
Say I'm coasting down the expressway at posted speed limit when
someone zips past me as if the driver's pants were on fire. Pick up
the toy gun and zap the offending car. If the driver has radar
detector on, he'd panic and slow down a bit.

I have a different question than the original poster had, for you. In making those coils, What do you use up the center of the coil to both insulate, and connect the lower mast and the upper whip? Assuming standard 3/8" 24 threaded connectors.....

We should have the examiners measure the size of prospective HAM's
dicks. That would get us back to the basics here that you've been
preaching about.

------------ REPLY FOLLOWS ------------

I agree. At least 100 wpm for Novice/Tech and something really hard
for General and up. Don't laugh, it's been done.

Also, lets have them memorize the Baudot code, demodulate PSK31 by ear
(no computers allowed) and launch at least one satellite into orbit.
They should be required to build an oscillator from a crystal set,
erect a 200 foot tower all by themselves and change the tubes in a
1500 watt amplifier while it is running at full output.

Hams today are a bunch of weenies.

Bill, W6WRT
who passed the 20 wpm test by about .001 wpm

Mostly brass 3/8" X 24 brass bushings OR machined bolts (Stainless steel) driilled in the center to receive the whip/mast. I generally use the brass bushings because they don't cost near what the SS does. Those specifically made bolts make the cost of the antenna much higher & and the bushings work well and are easy to replace if you should booger up the threads. That doesn't happen often, tho. But it makes it easy for any ham to repair one *IF* he should cross thread the thing. The center is black nylon that is machined to provide an open coil AND a support for the windings. This is done by turning a round cylinder of nylon to the correct diameter, then milling out concentric
grooves {sort of like this) } all round the form. This makes for both an "open" coil as opposed to winding the turns flatly onto the round form AND as a support for it. It then lets you clip onto the coil turns the same way of Henry Allen's Texas Bugcatcher. Then I thread the ends of the form to receive the bushings and secure them with SS screws so they can't slip. Then I wind on the wire (usually #14 tinned copper wire) in the grooves so it remains in place. I mostly make screwdrivers, but I make these for folks on request. I guess it may because of the cost of a screwdriver OR because some of us only operate a few frequencies or bands. It costs about half the screwdriver (of which mine are quite a bit less in cost) $500 for a screwdriver? WOW! I can't afford that, so I make a few antennas partly for $$$, partly for fun. It IS supposed to be a hobby! :) I have made some for a couple of Civil Air Patrol folks, one of which is on a building in Raleigh, NC as a fixed-base antenna. Turns out, they have some restrictions on dipoles, but the airport authority would only them do up a vertical. So, I made a mobile whip for them and they had enough metal up there for a nice counterpoise! :)

Email me under the "Reply" and I will send you a couple of pics if you like. One CAN use bigger wire if desired, BTW.

hi

I was wondering, if i designed a horizontal center fed dipole... w/a sorta fan say a few legs for 10-40m... but

instead of just attaching coax, i attached a sgc tuner at the feed point

would i expect the dipole to resonate"" as one would predict if feed directly via coax ex the 40m leg resonates on 40 or would the tuner 'grab' different ....??

tnx

naturally a single wire could be tune very well w/the remote sgc but i ponder

2865. replacing plastic parts of beam

Hello Group,

I recently bought a used Cushcraft A3S. The metal parts are in great shape and show little corrosion or wear. The plastic caps on the ends of the boom and on either end of each trap are brittle, shrunken and falling off.
I have emailed Cushcraft to see if they can supply replacements but it occurs to me that there may be an alternative solution. I don't want to put it up in it's present condition but I don't want to wait too long as winter will soon be here.
Can anyone suggest a good replacement option? Thanks!

If you were using the fan dipole with a tuner attached to the feed point, the tuner would try to establish the best 50 ohm match from the coax to the complex impedance presented by the antenna. The frequency at which you are trying to tune, and the complex impedance of the fan dipole at that frequency, will determine whether the tuner can match the coax to the antenna. One particular wire of the fan could dominate, but the tuner will try to match the overall impedance.

And we should insist they learn Swahili, Tasmanian, and in all
honesty, speak in binary proficiently. . . Well, one has to learn how
to beat upon a railroad track with a rock for CODE, might as well take
in the more simple aspects as well, huh?

My computer does CODE better and faster than you can `Slow. . . So,
what does that make you then? A Slacker or just a stupid agitator?

There is NO NEED for anybody to learn CODE. Not unless they WANT
to. What the hell does CODE have to do with SSTV? Or Packet? OR
Phone? There, I gave you THREE aspects of communications via "HAM"
that harbors Absolutely NO use of LEARNING CODE in any way, form, or
shape. Can you truefuly offer me as many NEEDFULL aspects of HAM
Radio which demands the use of Code?

Absolutely NOT!

In that regard, your very "hobby" denounces Your insistence upon
CODE, as a requirement, as arcade and dusty as a dead rat's fart.

We are NOT living in the 1920's any more `Slow. . . It DOESN"T
MATTER ANY MORE if People can beat on a railroad track with a rock or
not. NO ONE HAD THE SHIT WE HAVE TODAY, THEN! Hells bells `Slow, I
said it before and I'll state it again. The Damn CELL PHONE is
Cheaper and BETTER at communication than any silly HAM station in the
world! And it doesn't take no bloody HAM license to use it, ether.
Just a simple bank account.. . No wait. . Not even that in some
cases. Just a wad of dollars in your grubby little fist will suffice,
and there's No waiting on Sun Spots ether!

Honestly Slow, its people like you who make me want to sell my radio
station for a 1911 colt. . . They don't do CODE ether, but its damn
good with Binary!

Try the local hardware store and see if they have any plastic pipe
caps, or tubing caps in the sizes you'd like.

I capped off the end of my Ringo with stretch tape one year thinking this
would be a temp fix until spring. Well the fix has lasted 10 years and still
looks as good as new.

Kevin -

Yes, you have many alternatives.
Cushcraft did offer stainless hardware kit for the older A3 beams (before
A3S) as well as a plastic replacement kit.

What ever you select -- make sure it is UV resistant !!

Other suppliers -

Car Plugs for Tubing -- they have everything for tubing caps !
COF series will likely work !
http://www.caplugs.com/

DX Engineering
http://www.dxengineering.com/default.asp?DeptID=33
Seal the ends of your boom, tubing or pipe with our vinyl caps. Sizes fit
from 1/8 in. to 3 in.O.D. By keeping moisture out, you can reduce corrosion.
For those in colder climates, you can prevent water from collecting in the
tube that might freeze and split the tube.

Made from a strong UV rated material, they will withstand the abuse of
nature and keep your installation safe and good-looking for years.

Good luck with it.

w9gb

How about just filling the tube ends with silicone RTV? You can get a
whole tube of the stuff (for a caulking gun) for a dollar or two.

2874. Requirements to talk?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-26 20:45:00 UTC
From: "Fred Furlly"
Message-ID: <e2sjm2le2qoqsej7fmtl9eihnlnjhpsmvg@4ax.com>
Source record: 49096

Ive seen an arguemnet here which I find inlightning. In regards to using a two way radio, in English terms, A"Wireless", I ask what is the description of one of these devices in the first place?

From all that I can obtain, it is a device in which one can communicate with another via electronic or magnetical means with another party, completely devoid of any connecting wires between the two and over great distances.

I guess that's pretty simple and to the point. The very basic and simplistic view of things. As long as one can communicate with another by using some sort of signal derived from electrical means, and by not being physicaly connected together, then that is what this is all about, correct?

Well now, I have seen an issue which we all know about, but some how haven't acknolaged or reconized. Its just sitting there in front of us as bold and noisy as it can get! Even with our radio stations, the band width for most of us, is blocked off from access. Its the bloody Cell Phone!

By all descriptions, it is still a Radio! A Wireless device! And it is pretty complicated by all means as well. It is a digital multiplexer over many channels which can leap and lock onto several receive/transmit stations at once, jump between frequencies automatically, and digitally multiplex with who knows how many other people talking all at the same time, and for the most part, do a damn good job of it all around! Not only that, but there are satellite versions of the same thing too!!

Now the real fun comes in here. One does not need any sort of license to operate this device. There are external antennas available for them, some with awesome gain up in the 18 - 25 DBI's, and there are amplifiers, again with some real serious power output. . . All without any sort of license of competency and no regard to who they are radiating or where. All of this is totally "Above Board" and Perfectly legal in every sense of the word.

Now here we are. Working frequencies below and above this notch in the bandwidth. We have all sorts of laws and rules watching our every move. We have classes and social niches denoting who is worthy and who isn't. We have extreme prejudice against those who use certain bands and others who haven't the knowledge of what is call CW in our world. And that's not all. Not only do we police our selves to the point of extension, but we insist that the government jump on the bandwagon and exhibit the same prejudice toward the same social

classes which we have dredged up for ourselves, and for no more reason than because somebody's wanting to exert power, control over somebody else.

Am I missing something here?

Cell phones can reach every place on this globe, and without all the fuss and problems, and equipment involved with the aspect of HAM Radio systems. There is no licensing. There is no social grouping (Other than who owns what brand or color of phone.), and it operates right smack-dab in the center of the upper bands! Without any License or Competency Requirements!

What makes them so immune and us so vulnerable?! I know we did this to our selves, but isn't it time to knock off this childish Hoo-Ha and get down to the real brass tacks? For us to knock off the silly and time wasting of pointing fingers and strutting around like a stupid ol' Bandy Rooster in a muddy barn yard?

I always thought that being involved with HAM Radio was more than a social "Click", and that it was the passion for the extreme "Art" of Radio. Propagating the science. Furthering the technology. Not bantering around about who can or can't tap out a word with coded beeps, or who uses what frequencies.

People, I believe we have lost our way. We have lost sight of what this is all about. This should be a Brotherhood and not a Brothel stewing pit of spite and pride of empty or shallow socialites. None the less, where ever I go, I find the latter in a greater number than the former. And here I thought we were all here to help out each other. . . Not abuse each other.

So, tell me. Where did I go wrong? If Cell Phones can have no regulations on usage, and its free reign on pieces and parts, and usage, . . How come we are so incredibly regulated? Not only that, but why are we tearing our selves up in the process of simply trying to get along?

What's wrong with this picture?

Caution: Many silicone RTV formualtions have acetic acid -- which will eat at the metal elements (aluminum). Also unless it is an outdoor (UV resistant formulation) - it will quickly degrade in outdoor usage.
Just get the correct caps - they are not that expensive.

Many amatuer radio suppliers -- are very slow (to the point of not responsive) to e-mails.
Pick-up the telephone, call Cushcraft and ask for Ed Hammond (in charge fo amateur radio sales).
Tell him what you need and tell him you have antenna on ground and need to get it back up ASAP - before winter. IF he balks, tell him thanks -- but you will call DX Engineering for those parts.

Then call DX Engineering and they shoud have them shipped out within 48 hours.

Hey Slow Code,

Did'ja totally forget about the 2 meter band? Oh yea. . How about
the 70CM band as well? Boy-O-boy Slow, I tell ya' right here and now,
I've heard just as bad "Ratchet-Jaw" or Drooling idiots who think
they HAVE to talk on those two bands, (Which of course require
Expensive Equipment and Testing with Licensing.), as I've ever heard
on the C.B.

I swear Slow, you just absolutely refuse to live in the real world,
don't you? I'm beginning to believe we're going to have to pump you
in some sunlight real soon before you go totally blind! ! !

>SC

HAhaha! You are SO Stuck on the CB aspect of things.

Talk about a One Track Mind! Wow! You are SO Paranoid about this
`Slow.

Hey, think if it this way, and you MAY find peace in the
realization:

Real HAM Equipment costs BIG-BUCKS. LOTS of $$$, and is quite a bit
of a hassle to hook up properly and make work correctly. There is
naturally a learning curve in which people just Have to pay attention
to. That, as well as a pretty hefty drain on the ol' bank account.
Don't you agree?

Next realization is :
People are naturally LAZY, Stupid, and CHEAP!

SO, if you put it together, it goes something like this:

CB's are CHEAP and PLENTIFULL. They're EASY to set up and run. Plug
into the cigarette lighter, toss the antenna on the roof of the car,

push a button and talk into the mike. . . Pretty straight forward and, well, stupid. Correct? And, did I mention their damn cheep? $50 and you are on the air in grand style!

Ham radio. .. Humm, lets see now. Even at the "Lowest Level", you actually have to sit down and read something! Oooh. . . That takes effort! And, it's still going to cost over $200, JUST for the Radio. Not very easy for a Red Necked Ratchet-Jaw to afford, (Who has trouble just keeping beer in the 'fridge.) Next, one has to go and buy the antenna too. .. Hummm. Another learning curve here again. What type? Horizontal? Vertical?? And being that the system is pretty darn sensitive to begin with, they have to take time, and again, LEARN how to set it up properly to even transmit. And if they burn it up in the process, WHO CARES?! They'll quit right there and then. That'd be a Good Thing, huh?

Next there's learning the bandwidths, repeaters, and patches. Its just not punching a button from 1 to 40 and listing to somebody talk then joining in. . . One has to fiddle around with it and set the particular frequencies and splits. Moreover, every region is different, Unlike a CB. It's something that one just doesn't have time to do while driving down the road, like blindly spinning the dial on a CB. It's just too much hassle, work, time, learning, and especially, WAY too much MONEY involved!

Slow, I guarantee you that if some how, they drop CW, HAM Will Not Ever become like the CB is now. And for at least as many more reasons as I brought to light here.

By the way Slow, "Paranoia" is a metal illness that's easily treated with drugs. . .

I want to built an antenna to receive weather images. I have done this before using a simple dipole antenna. This time I was thinking of using a pair of crossed dipoles and wanted to know if it would be best to configure them as a circular polarized antenna feeding them 90 degrees out of phase or as a turnstile antenna with both elements fed in-phase. I have an old vhf aviation band converter that I think I can optimize for 137Mhz use. I think the only thing else I need is a PC with a sound card and the right software. This is the first time my daughter has ever asked me for help with a GS project so I had better do this right.

A turnstile antenna has both elements fed 90 degrees
out of phase.

> Gary N4AST

I have some experience with an arrangement like this using a different auto-tuner. Four different freqencies were suppose to be covered that were harmonically related. The antenna was cut to resonate as a 1/4 wl antenna on the greatest frequency. As one would expect the tuner had problems matching when the antenna was an even number of 1/4 wavelengths long. The immediate solution was to add more wires that were shorter than the origonal by 1/2 and 1/4. With this arrangement the tuner had no problem loading into the antenna. Probably the simplest solution would be to select a wire length that is not resonant on any of the desired frequencies so the tuner would not be trying to endfed an I(1/2) wl antenna at any used frequency. Of course using the single wire could also be a problem because at the highest operating frequency it could be 1wl long or longer and exhbit an undesirable

radiation pattern.

Thank you to everyone who responded!

I expect that Cushcraft would send the same parts as supplied with a
new beam. They were not very robust.
The traps are 1.625" so it looks like DX Engineering is not an option
based on what I see on the website. If Caplugs do small orders, that
might be the way to go.

Make sure that your converter has wide enough bandwidth.
I built a turnstile antenna but found it almost useless. If you have
time, check out the web for quadrafilar helix designs. I used this one:

http://perso.wanadoo.es/dimoni/ant_qha.htm

Oh, My gosh, . . Dick!

Don't you consider the SIZE of an auto to be a limiting issue here?
Just because there is a square inch of space, you Actually try and use
that as an example that it should be allocated to parking a CAR?! You,
sir, are trying your very best to compare apples with bulldozers! Duh!
Can't you at least Try and keep the topic in the same ball park?

I guess I see why some people just can't get a grip on reality.
Sorry for even bringing the topic to light. No matter how much
schooling some people get, they still remain total idiots. . .
Absolutely NO common sense AT ALL!

How about this then. . .

If it takes a man and a half a day and a half to build a boat and a
half, how long would it take a monkey with a peg-leg to kick all the
seeds out of a watermelon?
. . . A hot air balloon, because it hasn't a rot tiller attached!

There you go, Dick. That makes just about as much sense as the Crap
you spouted off with.

Geez! Moronic-Idiots abound!
("Moron". . . Look it up in the dictionary.)

Well virtually everything!!

A licence is required, and is held by the network operator. Users are covered by this licence. The equipment used must be type approved and some of the add-ons that you talk about are not actually legal.

So cell phones are not the free for all that you describe, it is a licensed service and tightly regulated.

Hi Walt,

Thanks for your reaction. And yes, I found your articles already some time ago. I missed the notes on the bifilar, but will study them again carefully.

Again, thanks,

Sam

------------ REPLY FOLLOWS ------------

I don't think that would end the endless harping about CW on this or
any other newsgroup. If it were ELIMINATED however, few if any would
be demanding it be brought back after a year or two had passed. It
would be a dead issue.

I hope.

Bill, W6WRT

Hi Jimmie

A turnstile antenna with reflectors is easy to build, and it works very
well for APT image reception from NOAA satellites.
If you build your weather satellite station from an aviation VHF receiver,
you wont be searching for perfection. So, I strongly suggest that you
avoid learning how to build a Quad helix.
If you have interest in learning about designing antennas for APT imaging,
I can show you how to construct an APT antenna that works better than a Quad
Helix . I have an "Internet buddy" who publishes alot of the information
I send him about the antenna concept that works a little better than a Quad
Helix. He (Patrik Tast) publishes the data at
http://213.250.83.83/~jerry/.

No Sal, You'd still be a retard. Doing ATV doesn't any require skill, and
it doesn't have it own test element either. A CB'er could go ATV, maybe
thats why you're good at it.

Come back after you learn CW to 20 wpm, and I'll pat you on the back and
say "Welcome to Ham radio, Well Done."

You need both to be a well balance operator. If you're willing and
motivated enough to be able to learn and communicate with CW, you're also
more likely to be motivated to advance yourself technically in other areas
of radio as well. You won't be one of those unmotivated no-code appliance
operators you hear on repeaters who spend their days kerchunking all the
machines in the area.

Why do you anti-code test people always spew the same dumb ass arguments all the time? The repeaters went down hill after the code requirement was eliminated for use of those bands. Hardly anything technical at all. Most of the retards up there aren't moving forward tecchnically. What makes you thing the same thing won't happen on HF? It will happen there too. We'll have fewer quality operators.

You say the things you do just like all the other dumb it downers say, You think CW is preventing the growth of amateur radio, and it needs to modernize. The CW requirement isn't preventing the growth of amateur radio, Laziness is.

I know you're right, Requiring good operators will kill the service.

Hams just want to be appliance operators these days and they don't want license exams that will interfere with them getting to those appliances even though it means being less skilled. I don't see anyone modernizing like everyone says is happening. They just get their licenses and grab a microphone. What percentage of hams have a computer connected to a radio? Probably less than 30%. Hams don't want to modernize. Guess we just have live with inferior operators on the bands from here on out. Then again, maybe hams shouldn't be required to be knowledgable or have skills. Requiring skills and knowledge is too old skool. Everything must be outcome based these days, even licensing. It ain't like we have to help out in emergencies or anything. It's Quantity, not quality. We need more hams even if they aren't skilled.

It's got to be incorporated into the exams then, otherwise hams aren't
going to learn and do it. If ham radio is to modernize hams must be
forced to modernize. CW isn't preventing the modernization of ham radio,
Laziness is.

Look at the no-coders on the repeaters. Many of them have been licensed
for years and they ain't moderizating. They're no better than they were
the day they were first licensed.

The passing score on written exams need to be 85% and double the number of
questions on each test element.

I push for quality hams. If you don't like quality there is CB. Let's
not turn the ham bands into CB

I most certainly did not start it. I'm the nicest person on usenet.

I'm here to help guide and motive people on how they can make themselves
better radio amateurs, unfortunately, some of those I'm trying to help
prefer to be stupid and lazy, and they flame people that try to help them
and they are down right rude. You can see the no-code license was a bad
idea, we need to require all hams pass a code test to bring intelligence
and civility back to ham radio and the repeaters. I prefer getting the
code requirement back up to somewhere between 13 and 20 wpm for all hams.

Right. Eliminating the code requirement for the Tech license was a bad
idea and it let riff-raff on our VHF and UHF bands. They need to require
passing a CW test for the technician license again, or make the no-code
license one year non-renewable.

2926. antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-28 04:56:04 UTC
From: jawod <jawod@fuse.net>
Message-ID: <425d6$456bc225$4831cf4b$6390@FUSE.NET>
Source record: 49000

Out of desperation, I thought I'd post SOMETHING (ANYTHING) with the word "antenna" in it.

I am preparing to set up a 2nd wire antenna at approx 90 degrees from my G5RV. This antenna is a purchased folded dipole from DX Engineering. It'll be connected to 400 ohm twin lead to a 4:1 Balun (DX Engineering again) and then RG8/U into the shack.

Is it better to place it 90 degrees from the center or from one of the ends? The ARRL Antenna Book shows both methods.

Thanks to ANYONE that answers "en forme"

John

Hi John,

Why all the care for technical description, and then form a question
appealing to aesthetics? Better?

"Better" is the parent to all answers both planned and ill-conceived.
I am forced to fill in the rhetorical blank left there as to you
meaning "would there be any impact that exceeds 1dB on way or the
other if the antenna were placed, say, diagonally to the G5RV."

Probably not.

However, this direct answer returns us to the semantic word-chase of
just what is meant by "better" and to what degree it is measured.

Another fill in the rhetorical blank: "would it affect the tune of
both/either to more than 10KHz? if the antenna were placed, say,
diagonally to the G5RV."

Probably, but "better" is relative to the distance in terms of
wavelength, and as the G5RV is a multiband antenna, and the new one
comes without pedigree, then that relativity is strained.

However, you do not express any inclination for the diagonal, but it
comes by association with center placement vs. end placement. The
crossed antennas of dipoles find each in the other's null; however,
what of dipoles crossed not like an X but rather like a T, or an L?

Interesting question that could be easily examined in 10 minutes by
the free version of EZNEC. My aesthetics demand a 1db variation or a
10Khz shift. They are met on the one, but not the other - this says
nothing of your sense of "better." The T and the X lead, whereas the
L and especially the diagonal push the envelope.

Yea. Morse code goes wayyyyy back. Clear back to when the natives were beating on hollow logs. Depending on the way the wind was blowing, they could talk to aunt Ug, or Cousin UG, or even their brothers uG and Grunt.

All I'm trying to get at is there are more than one way to communicate. CW in the world of HAM is definitely and ONLY ONE way to do so. How about this then, just to make it even:

Everybody has to set up and communicate via SSTV at X number of frames per minute, just to offset the requirement for CW. Equal time for equal privileges! Just like the politicians trying to get votes. . . Every radio and TV station has to offer equal time to each person and each issue. No one issue is more important than any other. . . just UNLIKE Ham, where CW rules and all others Drool. How darn lop-sided can it get!

Please now, don't get me wrong. I don't dislike Code. I strictly feel that it's blown WAY out of proportion and has become an excuse rather than a feature. One has to step back and realize that there are more than one way to communicate with somebody else, and that there is no perfect or required way to do so, UNLESS YOU OWN A HAM RADIO. .. . Geez folks. Isn't it time to let that poor ol' dead horse finally lie down?

Fred

CW is way tough to learn `Slow. . . ANY Idiot who wants to try to
enter the world of HAM will be totally filtered out by that one, huh
SC? It's BUILDING Advanced Systems that's the easy part. That, and

launching new and improved satellites, (Stupid Rocket Science is for Babies! Right?) That Big ol C.W. requirement will be the solid bastion against any unwanted foolish sort of person trying to gain entry to the Wonderful World of HAM, . . . Forever and a day! Ain't that right, `Good Buddy! . . SC? G'me a big ol' 10/4 there `Slow!

The only thing that CW means is that one knows how to communicate via radio in the style which is reminisce of old telegraph lines from the early western era. Nothing more. It's like seeing somebody ride a hose dressed in a cowboy hat. . . You've GOT to have that damn Hat in order to ride a horse! Period! In the same way CW is to HAM Radio nowadays. Pretty stupid, huh?

Hey, I got a good one for you all out there in `Net Land:

Around my place, the HAMs are such a bunch of Butt-Heads that people wanting to learn how to code, TRAIN BY USING THE CB BANDS!!! You see, that way they don't get their butt's chewed out by people "Who Know Better" and are "Professionals in CW", and so they "Quit mucking up the bandwidth with their stupid banter!"

Around these parts, I have to admit the CB'ers are a whole lot NICER group of people than the High and Mighty "Generals" and "Extras" ever thought of being. Just because they can tap out a code on a brass button with a tin shoe horn! How pathetic can one get! We might as well bring out some "Musical Spoons" too!

SC, have you looked up the word "Moron" in the dictionary yet? Its really not what you think you know about it. Honest.

I guess my 2m in the car qualifies as an appliance radio. My HF radios are mostly all old tube type. Real radios have a warm glow. I came upon a bargain that I couldn't pass up on a Yaesu FT-901. I'm still trying to decide if it's too new for me. I still practice with code tapes but I ain't getting much better but, I'm proud of my 5 wpm extra class licence.

Way to go Richard... That'll teach im to post anything about
antennas...

John, my immediate inclination without giving it any hard thought would
be to have them cross near the center lines as opposed to ends...
Now, I don't know about this using a balun as a transmatch... I
personally would not do that, but you may be perfectly happy with it -
especially if you only operate on one portion of the band and get the
antenna <or feedline> tuned so you have minimal reactance... BTW, you
will love the folded dipoles, they are just happy antennas...

Hello, and since the relative phase difference between the two loops is 90
degress could you not use a quadrature splitter/combiner? Mini-Circuits
and other vendors offer broadband hybrids. While DIY passive, narrow band
hybrids can be easily fashioned out of coax or lumped components, a
broadband device is more challenging.

BTW, you are asking for a device that can operate over a 30:1 frequency
ratio. I would relax that requiement if possible to 15:1 (2 to 30 MHz) or
less for a commercially-available hybrid. Also since you will be using
the combiner for receive only, RF power handling capability of the hybrid
should not be an issue. Sincerely,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

"You shore do talk pretty" :)

I meant "better" as in which arrangement looks best strung with
Christmas lights, of course.

Based upon your microscopic linguistic analysis, I imagine you use a
Microsoft product (at least conversing with you is similar to using
one). I use an iMac. It won't do EZNEC (unfortunately).

BTW (seriously), will the new Mac products work with EZNEC?

and by "work" I mean ...

Thanks, Denny

You know, I used the folded dipole first, but I think the G5RV
outperforms it, but not on 30M and not on 17M, two bands I have interest
in. Frankly my own interest in placement, while not trivial, is not
that important...I just missed antenna threads in the group.

Hello, John, and that link does not cover 0-90 degree (quadrature) hybrids which I'm guessing is what Bindy is after. A commercially-available broadband quadrature combiner/splitter is usually implemented using a 0-0 or 0-180 hybrid to which an all-pass network is added to achieve the desired phase difference out the output ports of the hybrid. Getting these devices to behave properly over a broad frequency range is somewhat of a black art and vendors such as Mini-Circuits and Merrimac keep these techniques to themselves. Sincerely, and 73s from N4GG0,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

http://www.vk1od.net/G5RV/

shows why the standard G5RV doesn't work well on 30m, 17m,
and 10m. If you want 30m operation, shorten the matching
section to about 20.5 feet. If you want 17m operation,
lengthen the matching section to about 37 feet. EZNEC
says that will give you a 50 ohm SWR of ~3:1 on 30m and
~2:1 on 17m. When I was running a G5RV, I had pluggable
lengths of ladder-line so I could vary the length of the
matching section from 20 feet to 36 feet for good
performance on all HF bands. Somebody (I forget who) used
remote controlled relays to accomplish the "tuning".

> just forgot about that, and tried to make sense of HAM.

If you mean the origin of the word "Ham' the best guess is from the ARRL
"Ham: a poor operator. A 'plug.'"

That's the definition of the word given in G. M. Dodge's The Telegraph Instructor even before radio. The definition has never changed in wire telegraphy. The first wireless operators were landline telegraphers who left their offices to go to sea or to man the coastal stations. They brought with them their language and much of the tradition of their older profession.

In those early days, spark was king and every station occupied the same wavelength--or, more accurately perhaps, every station occupied the whole spectrum with its broad spark signal. Government stations, ships, coastal stations and the increasingly numerous amateur operators all competed for time and signal supremacy in each other's receivers. Many of the amateur stations were very powerful. Two amateurs, working across town, could effectively jam all the other operators in the area. When this happened, frustrated commercial operators would call the ship whose weaker signals had been blotted out by the amateurs and say "SRI OM THOSE #&$!@ HAMS ARE JAMMING YOU."

Amateurs, possibly unfamiliar with the real meaning of the term, picked it up and applied it to themselves in true "Yankee Doodle" fashion and wore it with pride. As the years advanced, the original meaning has completely disappeared.

Hi John,

You obviously have never read an Intel hardware manual (circa MDS-80).

>BTW (seriously), will the new Mac products work with EZNEC?

This is something YOU should investigate. Mac now uses that one-and-the-same Intel engine. It is suggested in the press that it runs both operating systems. It costs more to do the same thing, but you get that cool logo. I prefer OpenSource servers, applications, and Linux. I haven't bought a M$ product in this millennium having experienced the Windows Me platform (Chairman Bill's fin du cercle joke on us all).

As I pointed out earlier, your question is answered in 10 minutes to all variations that I offered. That analysis even gives degrees of "better" as expressed in KHz and dB (quantifiable engineering terms commonly used in serious antenna discussion). As a spoiler, I will offer that the diagonal placement seriously disrupts both resonance AND gain to the tune of 100s of KHz and 3-4 dB. Of course, the qualifier "seriously" was meaningful only to me; that is, until I quantified it.

You still haven't offered us what the qualified term "better" means to YOU.

Hi Slow Code,
I don't normally open your posts (didn't note the sender this time) so I
don't
know if your the nicest person on usenet or a jerk. I do know that your
posts
seem to turn into arguments about personalities and disrupt the flow of
helpful
info that can pass on rec.radio.amateur.antenna.
I think this newsgroup is dying a slow death and suspect many are leaving
because

of drivel such as yours. I know I have contemplated dropping
rec.radio.amateur.antenna
off of my list, there is just to much on the net to put up with much
garbage.

>>You can see the no-code license was a bad idea, we need to require all
>>hams pass a
>>code test to bring intelligence and civility back to ham radio and the
>>repeaters.

I have been listening to the hams bands for years and noted plenty of room
for
intelligence and civility, I don't think no-code has added in more room.
The biggest problem I have noted is intentional interference on polite
roundtable
conversation.
Hmm! That seems to be what you do, only you do it on multiple
frequencies
(newsgroups) at the same time.
Mike

Hello both Johns. and one Bindy.

Here's how one person did it, and published in QEX November 1982.

"How to design wide-band RF Quadrature Network".

G.W. Horn, I4MK Bologna, Italy

It's not elementary, but he (and VE5FP/VK2BOX) made successful ones that covered 3-30 MHz nicely. Horn gives the equations that must be satisfied to accomplish the task.

If you have difficulty retrieving the article, the call book shows the call sign still active. Might drop him a line.

If you look at the web page where they tore it apart, you'll see it's little more than a microwave transistor oscillator using a DRO, another transistor for the mix, and a PIC microcontroller for all the "smarts." The PCB itself is a pair of (planar) antennas for Tx and Rx.

Clever idea... I wouldn't be surprised if someone thought it up and realized they'd make a lot more money selling the design (and consulting on it) to toy copmanies than just publishing it in, e.g., QEX.

2955. Shunt fed vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-28 21:24:07 UTC
From: John Ferrell <johnferrell@sprintmail.com>
Message-ID: <1a9pm259cmvosr8mo3rqdn53fetssfii3f@4ax.com>
Source record: 48928

Since things are a little slow here...
As I continue to experiment with my 28 foot vertical I attempted to try a shunt feed today. It totally escapes me how I might model it with EZNEC 4 but I do have an MFJ-269 to work with.

I set up the radials and tied them to the base of the vertical. I moved up the vertical from the bottom 55 inches. No real reason, that is the length of wire I had handy I fed the wire with the MFJ 269 with the coax shield on the ground side.

What I expected to see was some thing resonant between 6-8 mhz with a lot of reactance and who knows resistance. It did not happen....

What I did see was a resonance at 23 mhz with Rs= 48 and Xs=5 for a 1.1 SWR!

Dabbling with EZNEC seems to suggest there may be something happening like a 5/8 wave radiator but many factors had to be forced into place. So that leads to my question: How do you shunt feed a 28 foot vertical?

I work both Microsoft, OSX, and am learning Linux.

Not that it was asked for, but my experience has been that MS OS is
great if you have paid support staff to make it run, Linux is nice, but
every once in a while, it kicks us back to 1985, (sorry - unforgivable
in 2006) and when I absolutely have to get it done with a minimum of..
what is the technical term? Oh yeah - with a minimum of peckering
around, I'll use OSX any day.

And my G5 Mac is cool to look at too - inside and out.

Of course one can get the answer from a modeling program. Of course,
the modeling program won't tell *why*.

Here is a video of me trying to get a modeling program to tell me why my
antenna design worked like it said...

http://www.break.com/index/patiencechild.html

Dear "Bindy"

I have blocked so many for inappropriate messages that I might have
missed the point of this sequence. However, it appears from your last
message that your goal is to use a loop antenna or loop antennas to effect
an omnidirectional pattern from 1 to 30 MHz. "True" omnidirectional
antennas do not stay that way when above ground.

If what you are wishing to accomplish is a pattern that is independent
of azimuth using a loop antenna, then a much more simple solution exists -
at least over much of the desired frequency span. A (small) loop mounted
well above ground and oriented horizontally will do the trick. For most HF
receiving purposes, well above ground might indicate a height of between 0.3
and 2.5 WL. Mounting at 30 meters will do nicely from 3 MHz to 25 MHz.
Above 25 MHz there is not much to listen to. Below 3 MHz the pattern favors
nearby stations.

Again, I am not clear about the actual problem to be solved. It is not
clear if this is an amateur application.

If you feed it at zero feet, you get a feedpoint impedance
of zero. At the frequency at which the radiator is resonant,
i.e. about 234/28 = ~8.4 MHz, the feedpoint resistance will
increase as you raise the feedpoint. Somewhere on the way up,
it will be 50 ohms with some inductive reactance so you need
a series capacitor. It's a Gamma feed. It is easy to model
with EZNEC.

Hi John,

It is hard to imagine your antenna showed a strictly resistive,
non-reactive load over that interval where the radiator is only a
quarter wave at best. Fed at the base it should have some capacitive
reactance until resonance somewhere near the 40M band. Fed with a
wire at the height you indicate should show an inductive reactance
over the entire span.

>What I did see was a resonance at 23 mhz with Rs= 48 and Xs=5 for a
>1.1 SWR!

Sounds like your antenna base was not connected to the radials (you
were driving the antenna through the length of the gamma wire, and the
structure above it).

>So that leads to my question: How do you shunt feed a 28 foot
>vertical?

For 80M? About a 1000pF in series with the added wire. This still
says nothing of the resistance being sub 1 Ohm IFF your gamma wire is
on par with the diameter of the vertical element. On the other hand,
if it is very much thinner (and using half the capacitance), it stands
to elevate the resistive portion (to 30ish Ohms) into a match.

A more complete specification would tighten up the variability in
this.

Do any of you know anything about the RLM Electronics MN100-1 broadband HF antenna matching network? (see http://www.rlm-electronics.com.)

It looks like the same general idea as the T2FD antenna except the terminating resistor is in the box with the matching transformer.

They claim that the "four non-inductive balancing resistors" ("balancing" resistors?) will dissipate no more than 3 watts each with 150 watts of RF drive, which if true (big "if") would seem to indicate an overall efficiency somewhat better than a T2FD.

Gee, maybe there is such a thing as a free lunch. :-)

>terminating resistor is in the box with the matching transformer.

Hmmm. Looking at the photo, it's pretty clear that the lefthand terminal strip is just used to tie together the four resistors which make up the terminator (it's a series/parallel arrangement). On the right side, I can't tell whether all four of the terminals on the strip are soldered together, or whether it's two separate pairs.

>They claim that the "four non-inductive balancing resistors" ("balancing"
>resistors?) will dissipate no more than 3 watts each with 150 watts of RF
>drive, which if true (big "if") would seem to indicate an overall
>efficiency somewhat better than a T2FD.

That's definitely not something I would bet upon, for three reasons.

One is that it seems implausible. If the antenna itself is of a length which causes its impedance to be very high and reactive (and there _will_ be some frequencies where that's the case), the antenna itself will not accept much power and will present a high SWR at the feedpoint. The modest 2.5:1 SWR has to be coming from resistive loading of some sort, and by definition that sort of loading is entirely lossy. I don't see how they could get a super-high SWR down to 2.5:1 by dissipating only 12 watts out of 100.

Another reason is the fact that the manufacturer makes no claims about the actual efficiency of the antenna system, but instead acknowledges that it should not be expected to perform as well as a full-size antenna. (Even if it's only 25% efficient, it'd still be only one S-unit or so down from the performance of a low dipole, and the claim of "very respectable performance" wouldn't be outlandish).

The third reason is that the antenna layout diagrams shown on the "more product information" page suggest that there may be losses in the system other than those in the resistors themselves. Notice how all of the diagrams show the termination device mounted on an 8' ground rod, with one lead of the termination device being securely bonded to the ground. Based on the internal picture of the device, it looks as if this ground-rod bonding point is tied to one end of the termination resistors.

Notice also that all of the antenna configurations pictured are
loops, with a significant part of the loop sitting right on the ground.

I rather strongly suspect that this particular "matching arrangement"
depends to some degree on RF being coupled into the soil, in a lossy
way... these losses are part of what help "tame" the high/reactive
feedpoint Z at those frequencies where the loop is near a high-Z
resonance point and doesn't "want" to accept much power. This would,
if true, be slightly analogous to the way that radials for a vertical
antenna are "de-tuned" by soil losses if not elevated well above the
soil. There might also be a lossy path from the ground rod back to
the building ground in which the transmitter was being operated.

So, the losses in the resistors themselves may be limited to around 12
watts... but I have a feeling that the total loss is probably a good
deal higher than that, and (probably) occurs across the antenna's
whole frequency range.

>Gee, maybe there is such a thing as a free lunch. :-)

How so? Interested in your perspective on the 1985ish Linux issues.

And I have found that it takes less paid staff to support a number of linux servers than the same number of 2K or 2K3 servers. Clicking is much tougher to automate than simply writing scripts and adding them to crontab.

John,

Your terminology has me confused.

When you say you expect to see resonance between 6-8MHz, I understand resonance to mean zero reactance at that frequency. Then you tell us you expect to see lots of reactance. They are inconsistent.

Then you tell me that you expect to see a dip in SWR at the 1/4 wave length. I am guessing, but I think you probably mean the frequency where the vertical is a quarter wavelength long electrically.

If you drive the vertical at the base in series, you would expect to observe resonance (ie no reactance) somewhere around the quarter wave frequency.

If you shunt feed it further up, the shunt feeding arrangement acts as an impedance transformer, and it is unlikely that you will see zero reactance (ie resonance) at the same frequency as if you series fed the vertical at the base. A feature of shunt feeding typically is that it is reactive, and you have to tune out the reactance, adjusting the tap point up or down to get the desired feed impedance.

2972. In search of the "Tesla Antenna."

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-29 05:07:56 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <ekj4qs$2fih$1@news.ndhu.edu.tw>
Source record: 48945

Tesla's ether is rather difficult to define. Indeed, after researching and reading all of the data I could find on how Tesla viewed the ether, I only came up confused and guessing (I find the man to have been diabolically vague on this point.)

However, my best guess is that Tesla's ether is akin to a three dimensional model of "Newton's Balls of Force." For those not acquainted with physics labs and the balls of force, Google awaits you.

But, my guess is that Tesla pictured the ether as composed of particles, indeed, logic dictates it must be composed of some sort of basic building blocks (given you can muster the faith the size of a mustard seed in the ether's existence.) These particles are either resting against each other, or their "force fields" are (since we can't see them, we must guess-anything is possible.) Now, if a force is created which can act against these particles which the force contacts, the force will be conducted into the next layer of particles, then those particles will again influence the next layer of particles, and so-on and so-on. the same way Newton's Balls of Force react to a force applied to the ball at either end of the "string" of balls and conduct the force through all of the balls and into the far ball. Now, the force "flowing" though these layers of particles can be viewed as a "wave" but, when the farthest layer of ether particles lays against material of our universe (matter we can see, touch and which we consider real) it will act as a force of the particles of the ether "striking" or "impinging" the "real matter." Much like the far ball in the sting of balls of force would do if "touched" by some other material object at the far end from the applied force. Indeed, the force "flowing" though the sting of the balls of force is much like the "ether wave" I am attempting to describe here; when the "wave" has no more balls of force to "travel" though, the end ball containing all the force from the "wave" must move in an attempt to "dispose" or "convey" its' energy into some form of matter.

Now, liken all the above to light. Light travels as a wave in the ether, yet when striking a surface of some matter it behaves much as particles would when striking such a surface. Strangely enough, we still ponder this mystery to this very day. why light behaves both as a wave and as a stream of particles?

The above is kludged together and is difficult, probably, for others to grasp on a first reading, and I admit this reflects much of how my thinking is going when attempting to grasp how Tesla was viewing things when he wrote about "frequency", "vibrations" and such in his works and notes. however, from the above, I believe one can imagine how Tesla

would see an antenna interacting with the universes ether and "transmitting" its "wave".

Now, all of that said, how the "Einstein Antenna" would function would even be more difficult to comprehend. sometimes leading one to come up with "magic numbers" to describe it in mathematical terms.

But, if one ponders the above to terrible depths, one is left with the expectation of finding the ether's particles to exhibit no mass what-so-ever, and frankly, I find that impossible. go figure.

Or, consider I just made the above up! Or, I just dreamed it all! Or, Tesla never said any of that at all! <grin>

My perspective is that of an OS that occasionally makes me work as if it
was 1985. More on that below.

>
> And I have found that it takes less paid staff to support a number of

Ahh, the perspective issue! Agreed that getting to the command line
is a more efficient method, even on an Xserve. But I have to deal
with situations where I have to get a piece of hardware, anstall and
use it and any software needed, and meet a deadline.A real short
one. With the PC, we usually find that we have hardware limitations
(always cured by spending a few K), with Linux, we can spend a lot
of time looking for drivers, installing a program is always
exciting, and usually the deadline has come and gone in either case.

I use the Mac because I work with a computer, not get a computer to
work. I'll gladly concede that the other platforms/OS's are much
superior - certainly they must be, because they require a support
staff that knows many interesting and arcane things, and I just plug
away, meeting deadlines.

Mike:

There was a time when linux expected all hardware to know its job and have the internal software (firmware instructions actually) to do its job and leave the OS free to use its processor cycles much more efficiently. Linux ran like a race car back then, and the command line as opposed to the processor cycle glutton of the GUI aided this tremendously (or, I don't need all those cutsie windows, icons, themes and sounds!)

Windows tries to encompass and contain all the software necessary to do all things (mostly as dll's, ocx code, etc.) No better example of this exists, which I can think of, than the "software modem" as opposed to the hardware modem. The OS must handle all data compaction/encryption/de-encryption/de-compaction/"error checking"/sending/receiving/etc. and slows other processes down to accomplish this (or, why is my word processor dragging when the modem is on?), for the software modem. The hardware modem just does it all and hands data to the OS, or takes data from it for processing and sending. The 56K USRobotics Courier External modem was the prime example of such a hardware modem and contained its own processor and it was identical (I think) to the processor used in the first IBM computers (second generation actually, first generation used the 8086;s)--intel 80186's? This was one powerful modem! It's speed unmatched by any of the day...

Now, both linux and windows are growing towards a common ground where both OS's will contain all this software and become bogged down handling all the processes for all the hardware--not good in my opinion. But, it gives us cheap computers (the hardware is just basically ports and mechanics.)

Put simply, a hardware techs' job is to speed up computers operations by magnitudes. A software tech's job is to slow down the computers operation by magnitudes. You see this before your eyes, each year computer hardware is 10x faster, each year the OS is 10x slower, which results in very little if any net gain in "actual user speed", best seen when waiting for the OS to boot up!

My next favorite gripe is the retail takeover of the internet. I don't come here to buy things. Why not create a .ret (dot ret) in addition to .com, .net, .org? Then banish all sales to .ret addresses so my google searches don't return tons of useless chinese junk for purchase. If I ever want to buy online I will know to search for .ret sites! Oh well.

Hey! Way cool, CL! I Love trivia History.

One can learn so much this way without all boring people to death
with all the pointless and grueling details!

As for the original meaning, I agree with you on that part; it's
been forgotten and lost under the bed with the dust-bunnies of time.
However, I believe your suspicion on the meaning is probably more than

accurate, AND the "Spark-Gap" transmission gear of the earlier `Station Operators equipment list is quite true, which makes me stop and think about the more logical divergence of things, of which we nowadays find our selves in. . . If the Old Time Operators were outrageous scoundrels with their Spark-Gap technology, even if the technology failed to carry through to today times, the "noxious attitude about the ridiculous, mandatory 5 wpm Code requirement for licensing" has come through along with all the fervor and mind-numbing hatred towards humanity of these early-day "Phrekers". The personal need of these people to cram it into everybody's face in and rub it in hard, is still evident regardless of how pointless the issue has become with the REAL people in power.

Dropping the requirement down to 5 WPM is purely ridiculous and pointless. It only reflects the attitude of petty tyrants. . . Or power crazed, pre-computer era, Spark-Gap, Phrekers. =)

(That one was aimed Right at you S.C.) =) Pthttttttt!

Bawhahahahaha!

You are SOOOOO Full of yourself SC!

You bet! Its a good thing to know Code, and darn right you are to
be proud of Learning How to Code. . . But hey, wait a minute. . ..
What the heck makes you now believe that just because YOU wanted it,
and went out and learned how, that now EVERYBODY HAS TO LEARN IT TOO!?

Isn't that just a tiny bit selfish? Something akin to what the
Nazis' tried to impose on the world?

"My Shit's Really Kewl, so YOU have to buy into it as much as I did.
. . In fact, seeing how I have this-here baseball bat, I suggest you
had Better start feeling the same way I do or I'll just have to take a
moment or two and adjust your way of thinking!. . . Buddy!"

Again, SC, We all agree that Code is a good thing. Your approach
towards it isn't. Nor is your insistence that everybody has to learn
it or they not be allowed to use the radio. In fact, that's quite the
anti-social behavior you've got going on there, SC. `Nothing to be
proud of, . . . Good Buddy! Next, You'll probably try and say that
just because I'm not as white as you, I'm not aloud to use the radio
ether? Huh?

No difference, SC. No difference at all.

Hey SC, do you have a masters degree in vehicle engineering? No??
Well then, you are not allowed to drive your car anymore, ether! We

got to keep the "Trash" off the road or it will become like a go-cart
track. And we all KNOW what go-cart tracks are like, don't you?!

2983. FM Transmitter for CD Players?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-29 12:39:44 UTC
From: "W. Watson" <wolf_tracks@invalid.com>
Message-ID: <kcfbh.5246$1s6.1105@newsread2.news.pas.earthlink.net>
Source record: 48956

I just bought an MW FM transmitter that is battery powered. It allows one to hook up the output of, say, a CD player to the headphone output, and transmit the signal to select FM bands. This is fine for the most part, but I'm wondering if there are units that have wall warts for power?

Well, I guess I'm lucky in that respect, I just need to keep the email,
web, DNS, etc. running. The hardware involved is never an issue, since
the ethernet card is about all the OS has to find drivers for, and
installations of current RHEL and its derivatives are a snap to perform.
RAID is the most important "odd" hardware in my world, and it is
thankfully transparent to the OS in most cases.

Go to C Crane's web site, which I believe is ccrane.com. They used to
have a unit that ran on battery or a wall wart.

2986. Re: In search of the "Tesla Antenna."

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-29 13:11:18 UTC
From: Denny <k8do@mailblocks.com>
Message-ID: <1164805878.693294.32030@h54g2000cwb.googlegroups.com>
Source record: 48959

Hmmm, John... Physics and our belief system about what these things we measure with electrical meters and telescopes in the physical world really mean changes with time... We went from the animus earth <placating the trees, rocks, etc.>, to placating the gods in the heavens above, to earth air water and fire, to Phlogiston/Aether.. Then Einstein, Dirac, and many others, came along and this group decided that there was no phlogiston, et.al. and we went to the concept of the empty space, open universe... Then the telephone guys had problems with noise spoiling long distance transmissions and detected low level background radio signals which caused the physicists to again revise their equations and declared it mean't 'kablammo' a closed universe, eternal expansion, and heat death.... And since then
the Big Bang has been dragged along, patched up, shored up, repaired, and redecorated, until it looks like the house that Topsey built...
BTW, note that to go along with the expanding closed universe that Einstein had to revise a number of his equations to dump a nasty little term that implied that empty space was not empty, that it contained energy - and energy is mass... And unmeasured mass in empty space means the Hubble constant is all wrong... And whammo, down comes Topsey's house...

Now, to get back to antennas, the radio wave we launch off our antennas is a photon in motion... Like electrical charges in motion on a wire have a field around them, a photon in motion has a field around it... That force field we call an E+M wave... If we use instrumentation to measure the E+M field we declare that radio is a 'wave'... If we change our instrumentation so that it responds to photons instead of E+M forces, voila, we find that radio wave is magically now a 'particle'...
So, consider this: Your antenna is a magic box... You pump electrons down the antenna wire and it gets rid of this excess energy by converting the electrons into photons and radiating them away... Somewhere out there the photons ram into another wire, dumping energy into it... This magic box then reconverts the photons back into electrons, and you detect a signal...

OK, now the physicists find themselves back in the hot seat because new findings strongly suggest that each cubic inch (or CC's for you metrically handicapped types) of empty space contains a measureable amount of energy/mass equivalent...

*** An aside: For a non mathematical explanation why energy cannot be directly converted into quarks/mass, read Lawrence Krauss's book ATOM... Highly recommended by me..***

And other new measurements are interpreted that there is a Dark Force pushing quarks/mass/galaxies apart against the contraction of that nasty Gravity Field <can you say, "Phlogiston"?>... All of which has sent the phsyicists back to the loo where they now sit stroking their equations... Sooner or later they will exclaim, 'Voila!' and we will be presented with Einsteins scribblings with that nastly little term re-inserted for energy/mass in a vacuum and they will strut around declaiming they knew it all along... This has been the most fun to watch and chuckle at over my lifetime... After they proudly show their revised equations explaining all this within the next decade, I hope to live long enough to see the next wave of 'new measurements' that sends them thundering back to the loo...

cheers ... denny

2987. Re: Shunt fed vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-29 13:36:12 UTC
From: Denny <k8do@mailblocks.com>
Message-ID: <1164807372.219994.133020@h54g2000cwb.googlegroups.com>
Source record: 48960

Hey John... Glad to see you are still experimenting with the
vertical...
One answer is that you are shunt feeding a vertical monopole near it's
third harmonic tapped at about 1/8 wave above ground... Depending upon
shunt spacing and the diameter ratios it looks like you found the magic
spot for that frequency to transform to nearly a 1:1 match...
As one fella said to me long ago, I would rather be lucky than good,
any day...

Still, a better topic to read than most of the dreck on here.

I am homebrewing (if that term isn't overkill) a dipole and am using PVC joints...a T in the middle and straight connectors for the ends. Will these need to be treated (painted, etc) for UV protection?

Richard, feel free to give this one a pass. :)
You're a good guy, it's just that your prose borders on word salad sometimes (hold the pedantic dressing)

Source record: 48962

I need to build a 4 bay folded dipole like the one use on vhf/uhf
repeaters. The folded dipole is easy
enough to figure out but how do you get the 4 - 300ohm dipoles to
combine to one 50ohm feedline,
I have looked close as i can at these and there is no combiner but it
looks like maybe some coax
phasing stubs or lengths of coax inside the antenna support mask?

Hi Sam & Jerry,

I stand corrected, and thanks to both of you for detecting my error. As I told Sam, it's been 26 years since I worked on the QHA, and I simply forgot that the second bifilar fills in the null of the first, due to their quadrature relationship. Senior moments are arriving more frequently these days at age 88.

I live in a antenna restricted community!

I have put up a somewhat stealth antenna.
It is a 540 ft loop = 180 ft virtually lays on the roof and the remainder
360 ft is in my attic.
I feed this with 50 ft of RG58u at the center point (6 turns of the
feedline - approx 8" dia is used as a RF choke) running down to a manual
tuner.
The antenna in this configuration is about 1.5:1 across all the bands from
75m to 6m. I would like to operate on 160m, but the tuner doesn't cover
that band, and when I try to go directly the SWR is extreme and we don't use
it!
My questions are:
1] should I leave the antenna system alone as is? It works - but as a
wire system has its limitations due to the clearance off the roof?
or
2] should I purchase another antenna tuner that covers 160m - 6m. and
open the LQQP and make the antenna a single 540 ft piece of wire and ground
the other side?

The best explaination of this I have ever seen is contained in W1HIS .pdf article on yccc.org concerning common mode chokes. Dont let your head hurt. It is a big download but well worth the read. Chuck is a retired prof at MIT and did AR commuity a great service by publishing this. Transmission line vs. common mode is addressed in the early stages of this read. If you get hooked on this chunk of info like I did because of receive improvements and TVI redux be sure to read the footnotes. There is a wealth of info contained in the footnotes.

To give you some idea of the degree of improvement in receive noise floors....I am using a 33 foot vertical mounted 12 feet up with some elevated radials. I feed this with a Johnson Matchbox and 450 window line. Receive noise floor improved by 7 to 10 db after installing 3 common mode chokes in the feedlines. 1 at the feedpoint, one at the entry and one at the exciter.

I cannot imagine how much money I would have to spend in improved antennas and hardware to yield that kind of noise redux.

Here is the link:
http://www.yccc.org/Articles/W1HIS/CommonModeChokesW1HIS2006Apr06.pdf

BTW. The reason why I started this search on common mode choking was to reduce rfi in the shack. My installation is meant to offer minimum of tvi by being careful with my antenna placement which in my case means having it 12 feet above my transceiver. Not only did the rfi go away but all my rfi issues subsided on my entertainment devices as well. No complaints from neighbors either. On smallish city lots with open door entertainment systems makes it hard to be a good neighbor. This helped a bunch.

Best and good reading, Chas W7MAP/5

You are probably thinking of the 8088 (8-bit bus) used
in the low-end version of the first IBM PC. But the
"first IBM computers" were not solid-state. :-) Back
in the 50's, the IBM-650 computers used dual triodes
with a magnetic drum as the memory. The logic was
bi-quinary, somewhat like an abacus.

Is the perimeter of your attic really 360 ft?

That's a lot of wire to stuff in an attic (with an additional 180 feet
on the roof over the attic) and still resemble a loop.

Why not borrow a tuner that covers 160 meters and verify that it will
work before buying one? If the 540 feet is indeed a "loop" you should
not have to open one end for 160 meters.

Chuck

Cecil:

I am trying to imagine a USRobotics modem the size of my garage!
Probably was the 8088, a '186 would have been a bit of an overkill for
56K and a phone line (but the 8088 probably had head-room left over!)

Regards,
JS

One more piece. Back around 1953, my Elmer, (Shorty, SK, W5OLV - old lousy virgin), told me that the "ham" in ham radio originated with the way English cockney amateur radio operators pronounced "'amateur" as in "ham-ateur".

One note on antennas: W5OLV talked to those cockneys on 10m with an RG-11 fed 75m dipole. When I later learned that an 80m dipole used on 10m would be 4 wavelengths long, I thought Shorty was pretty ignorant. It's true that 1/2WL on 80m would be 4 wavelengths on 10m but I much later realized that 28MHz/4MHz = 7 and 7/2 = 3.5 wavelengths. As I remember, Shorty's dipole was ~117 feet long.

Sorry for the confusing terminology but I am confused!
The testing I have done so far with this 28 foot antenna has been
series fed. The results obtained have been consistant with the Eznec
models.

I believe my current direction requires I puzzle out the Gamma match
in Eznec.

I have unpainted PVC poles up in Michigan and they have held up for years with just a bit of powdering of the surface... If you are using the dipole for a year or three leave it bare... If you think it may be up for decades, spray with a dark color paint to block UV...

Stumbling across that condition has added to my confusion!

My dumb questions should show that the 28 foot stick still has lots to
teach me. I am beginning to get a little impatient to move on to a
permanent radial system and a taller antenna. Shunt feeding would
simplify lightning protection and physical mounting considerations of
a taller stick.

Hi Walt

I dont consider your statement to be an error. I suspect the bifilar helix is the closest antenna configuration Sam could find. A casual forum like this group has to be able to cut some slack. You made sense to me.

John,

For the moment, forget the term resonance, what it means, what is
resonant, and the importance or not of resonance.

Just make you objective a feedpoint Z = 50+j0.

>The testing I have done so far with this 28 foot antenna has been
>series fed. The results obtained have been consistant with the Eznec
>models.

Ok, I assume that means YOU have created and run the NEC models.

So now model the gamma match, initially with zero capacitance. The
diameters of the gamma arm and and the driven element, and spacing are
critical parameters, change them until you have the desired feedpoint
R. Then insert a capacitor at the feedpoint to offset the inductive
reactance in the feedpoint Z.

Then build it, and see if you can't make it work.

>
>I believe my current direction requires I puzzle out the Gamma match
>in Eznec.

That is probably a lot easier than suck it and see experiments.

Owen

PS: When you have done all that and it works, go back to thinking
about resonance, and take a system view. In EZNEC you could explore a
solution for the same operating frequency with a shorter vertical, say
25', design the gamma match for a 50+j0 feedpoint, compare the gain to
the longer model and answer the question of whether natural resonance
of the driven element alone (ie without the gamma arm) is critically
important to performance of the antenna system.

A progress report:
I have not adapted your advice yet and I am going to have to break for a while to do some real work but here is where I am...
For ease in modeling I have a 2*28 foot (56 ft overall) free space dipole: This frees me from ground effects. I used #12 wire to simplify wire intersections. I have NOT experimented with spacing and wire diameters yet.

I will attempt to attach the Eznec file here in case anyone is interested.

TIP: to get a better view of the matching setup temporarily change the lengths of the +28 and -28 wires to 10 feet.

3016. 20m vertical dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-29 20:42:43 UTC
From: Dave <dwbridges@cox.net>
Message-ID: <1164832963.599575.138750@j72g2000cwa.googlegroups.com>
Source record: 48889

Picture 2 fiberglass poles, each 16.5 feet long, mounted
horizontally on top of a 10 foot long wooden pole, with a dipole cut
for 20m strung between them. The coax feeding the dipole is taped to
the wooden pole. Picture this antenna on top of a building, then
position the antenna with the wooden pole parallel with the ground,
extending past the edge of the building, and the fiberglass poles
extended vertically. A vertical dipole! This is what I'm thinking of
putting together for a trip out to a friends lighthouse, and the end of
the lower element should be about 30 feet above the water. Being above
salt water, I'm expecting a takeoff angle of less than 10 degrees, and
hopefully closer to 3-5 (or less) for some DX work.
I've never built an HF antenna before, but I have had success with
a 4-element 2m quad I built years ago. Does this design look like it
will work? Any and all (well, most, at least) comments will be given
their appropriate attention. Thanks.

Dave

3017. (OT) Military tactical comms: Harris v. ITT

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-29 20:47:36 UTC
From: junius <junjunius@yahoo.com>
Message-ID: <1164833256.190422.246930@h54g2000cwb.googlegroups.com>
Source record: 48890

I realize this is off-topic, but I thought that perhaps some knowledgeable individual (preferably with hands-on experience with such equipment) could give me an informed opinion on how ITT's tactical radio products compare performance-wise to those of Harris Corporation. Specifically, I'd be interested in any opinions of the VHF performance of Harris's current Falcon II product line (e.g. AN/PRC-117) and ITT's current SINCGARS product line, which both see high usage in the US and other militaries worldwide. Not interested in Harris's edge where multi-band is concerned; only interested in opinions on VHF performance. Speaking specifically to those who have used such equipment, any preferences for the equipment of one of these radio manufacturers over the other? And why?

Any informed opinions with regard to performance, reliability, drawbacks, ease of use, etc etc would be most appreciated. In essence, in what areas would one have an advantage over the other?

Thought I'd pose the question here, since we have some very knowledgeable individuals in these groups, some with military experience...

Apologies for the off-topic nature of the query.

Regards,

Junius

Keep in mind that the less your model resembles the real antenna, then
the less the results are applicable.

I am not sure that your dipole in free space is better or even as good
as modelling the vertical over perfect ground as a first step.

If you are using a 28' #12 wire vertical, then it makes sense to model
that, but if you are using a self supporting tube or mast of much
larger diameter, then you are modelling something else.

Gamma matches become impractical when they call for extremely small
tuning capacitors, so your challenge is to find a solution that uses a
practical tuning capacitor.

Start the search with a low tap point, equal diameter conductors, and
wider spacing. Move the tap point up to increase R. Check the tuning
capacitor required. Explore the sensitivity to changes in all three +
driven element length.

Hi Dave,

Sounds like a lot of work when gravity can do most of the fiberglass poles' job. Try a sleeve dipole (vertical, of course):

Take a coax and strip off 16.5 feet of its jacket;
Pull back the coax shield over itself (like taking off a sock from the top) back to the 16.5 foot mark and keep pulling it another 16.5 feet;
You now have an exposed inner conductor, and the coax shield rolled over 16.5 feet of jacketed coax (you need at least 33 feet of coax to do this). Feed this prepared coax with more coax (or simply use a very long coax with one connector at the transmitter).

This is where gravity comes to work:
Hang the inner/outer prepared coax over the end of the horizontal support, with the feed tracing along the horizontal support.

Same amount of wire, no need for the fiberglass and even if you may be closer to the waves, it hardly matters (unless you have 20 foot surf conditions).

Richard,

You forgot to tell him about trimming the folded back coax shield in order to account for the reduction in velocity factor. The folded back shield and the coax outer shield have a dielectric constant between them that is based on the cable jacket material and a minimal air gap.

You covered this quite well in an earlier post you made:

http://www.archivum.info/rec.radio.amateur.antenna/2005-10/msg00373.html

The original posters idea was easy to build and will work quite well horizontally or vertically. He should put an RF choke (coax coil or ferrite beads) near the feedpoint in order to reduce the RF flowing on the outside shield of the cable.

Roger

3022. Tower height question (moved thread from tower pro NG)

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-29 23:12:06 UTC
From: Merlin-7 KI4ILB <merlin-7@sc.rr.com>
Message-ID: <atobh.65629$HD6.42048@tornado.southeast.rr.com>
Source record: 48895

I will be moving my QTH next year some time and am planning my new tower.
I need to figure out the minimum height of the tower to work 10 thru 80 meter bands and 160 if possible. The tower I have now is only about 42' tall and I have good results from it. However I have nothing else to compare it with.
I can put up a dipole for each band but I think that there would be a lot of interaction between them.
Below is what I have now and I want to improve upon it however I want to limit my antennas to wire for now.
What height do you think I will need and at what height should I place each dipole? They will need to be inverted a bit.
Lets say that with the tower in the center, the ends of the wires and / or rope that holds up the wires is 20feet up and 120 feet from the center of the tower on each side.
X20'-------------tower-------------20'X

I like to play with wire antennas but let me explain my fan dipole in detail.
It has 3 elements a 66' a 33' and a 16' on each side of the feed point with an airwound choke at the feed point. It is not a normal fan. The wires are hung under each other with the longest on top and the shortest at bottom. They are spread apart 12 inches by pvc pipe, the first spreader is 18 inches from the feed point. The feed point is about 40' up and the end of the 66 footer is about 18'up. So the ends of the shorter wires are higher since they are hung under the 66 footer. (I hope I explained that well enough) I also have many buried radials that are also tied into the chainlink fence that runs about a square block (all my neighbors fences are tied together) I have worked Germany and several other places in Europe with it but I know I could do better with everyone's help here.

I want to do some long DX work limited to 100 watts on every band That I can.

The tower will be on a 1 acre lot but my sister owns 6 acres behind my lot and my parents own 2 acres to the right of my lot. So I have plenty of room for wire antennas and buried ground radials.

I can use one ladder line feed but the rest would need to be lmr 400 for hf and lmr 600 for uhf /vhf

Do you all think that I could get by with a 80 foot rhon 25g?

Ideas?

One more question, how will the guys effect the wire antennas? I do not think that I could afford poly guys.

Hi Roger,

I took a quick glance at your link, but I don't think I paid much attention to velocity factor (given all the variables). For all of a life of precision I've been devoted to, I can summarily toss off those issues (when data has already pounded me down with the weight of imponderables).

One way to approach this is to take SWR readings with the progressive rolling back of the shield over the lower jacketing. If someone could do this with a stepper motor, then we would have a new antenna design (new in the sense that it's new to/from me, and probably anticipated looooong ago).

Here is a better set of numbers. The antenna(s) involved are strictly
lab experiments. I have not worked out the details of putting the
source where I want it with a vertical, it would be in the ground
plane. The objective was to get a "feel" for the shunt match problem.
With your guidance I think I am on the right path.

My early conclusions (subject to change!) is that I don't want to put
too many resources into a grounded vertical antenna. It will be easier
in the future to match an insulated antenna. If one already has a
grounded tower available it might make good sense to shunt feed it.

So, can you bend it down a few hundred megahertz into the amateur 10GHz
band? Without spending more than you would for a Gunnplexer?

But if we push for good tests, new hams will have a leg up and we won't
have to elmer them as much and if we push for really really really good
tests, they can elmer us after they get licensed.

Slow Idiot:

You must be the most vile, degraded, despicable, disgusting pos (pos = piece of chit) which ever fooled their vec and obtained a license. You are disgusting beyond description. I pity your neighbors, I believe they have ALL had problems with you, I believe the police, sheriff and county officials in your county all know you. I bet your children despise you, if your wife is still with you--she is a saint! You are not just a lightweight idiot, you are a complete idiot. You do the name IDIOT! much service, you never cease to be complete and an ideal example of an IDIOT. I bet some here do not realize how much you tax the services of city, county and state with your ridiculous and childish behaviors, wants, fits, temper tantrums, generally foolish behavior, etc.

You would truly be a very funny joke, if you were not such an example of human depravity. You remind me of the disgust I feel when I see child molesters and people masturbating in public, drunks, hopeless alcoholics and drug addicts, disease infested whores, etc.

I would truly like to leave you with a picture of how disgusting, reviling, sick and putrid an individual I view you as, but mere words could never paint a proper and complete example. You are beyond words, you are beyond my most vilest visions of disgust, you are a pinnacle of chit!

Now, all that said, I think you are pulling our legs, no one could possibly be so disgusting and stupid--you are just pretending! <grin>

The ARRL book, FM and Repeaters (1970s) included information on building a
"phasing harness".

Kevin Custer, K3KKC has some of this information at his Repeater Builder web
site:
http://www.repeater-builder.com/rbtip/exposeddipole.html

Here is a great UHF solution (DB Products commercial 4-bay antenna) -- nice
price
DB Products phasing harness for 4 bay UHF dipole, New in box. 455.0 MHz
center frequency. $50.
http://www.ipass.net/hockaday/com.html

Slow Idiot:

I am going to do you a BIG favor. You didn't know I was psychic, did you? Well, I am, let me give you a reading...

You are the kind of guy who impresses young children, old women, and mentally and technically challenged individuals. You realize that you have that special autistic ability of being able to rap out, and quite profusely--probably, those taps in code. You were quick to realize that individuals with low self esteem, persons of low self-worth and individuals seeming to lack any skills what-so-ever were VERY impressed by such an ability--of course these individuals also failed to realize just how stupid it was to "hero worship" such a trivial ability.

However, for one such as you, un-remarkable in all other ways type of guy, no great IQ, no other real skills or abilities, a general inability to get along in the general society, etc... for you, this was a way of "feeling special." But, it came at a price, it blinded you to how simple others with real abilities, high IQ's, great skills, good social abilities, etc. viewed you. You simply shut your ears, your eyes and your mind to reality; you finally reached a point where you were unable to care, to see... You came to live in your "special world" where you are quite special, talented, skilled, etc. You live there now, you think you enlighten us with your wasted "text verbiage" here, you draw upon others good will and tolerance, you keep thinking you have a great message to impart to us. That soon a revelation will strike us and we will all recognize you for the great man you think you are...

This story goes on and on, indeed, it appears as if it is one of those special, un-ending story with you painted as lead hero, painted as such by you, yourself--of course... well, even you can see where I am going with all of this. And, you know it is true. You know we will be watching your behavior in sheer unbelief and amazement, you realize you really do look quite stupid. You realize you have painted yourself into a corner which you cannot escape. And, it dawns upon you, you have nothing to lose, all credibility is lost--you may as well continue on your present course--there is nothing to be lost--it has already been gone for quite a time... still, your only two choices is facing your peers disgust, or quitting, and I am betting you just can't quit. I have never seen an individual like you who was able...

Good luck...

P.S. I am really not psychic--but you already knew that... It is just that such small intellect as you display is simple to define... but you

knew that--already. You are simply trapped by the particular mental disorder which plagues you, your world is small and therefore you expect it to be so for all others. You are now but an actor on a stage--your part has already been written, you now only perform your part... a limited performance, a small performance, a vile performance, but still--it is yours, and it tells a much larger picture about you--how much better it would be if performed for people who actually cared...

Ramsey has FM kits that are easy to build and, after I did three of them,
reliable. I think I did the FM-10C.
http://www.ramseyelectronics.com/hk/default.asp?page=amfm

In San Diego, Gateway Electronics sells them off the shelf. If you have a
medium to large elex store nearby, inquire.

It's ironic how he thumps his chest, claiming to be the bearer of all
that is good and true in the ARS yet he directly and blatantly
violates the very standards he champions. For example, the very fact
that he uses completely off-topic newsgroups as his soap box is
exactly the same as operating a radio on completely un-authorized
frequencies and power levels. His mental disorder prevents him from
seeing this.

It's quite sad, really. We should pity him.

It doesn't take a damn bit of knowlege of electronics, radio, propagation or
regulations to learn cw.
So how is cw gonna prevent the dumbing down of ham radio.
Why are you not stressing a need for better testing for technical
competentcy to prevent the dumbing down?
There are a lot of engineers, technicians and hobbyists who allready know
electronics who might be interested amateur radio, but don't have time or
interest to fool around learning code. Once licenced some, maybe many, of
these people would develope an interest in cw.

Yikes! I think you're right. I can probably cut them off at the pass this morning. They said it would be shipped today. I was looking at the picture thinking that was the whole unit. I see some other units, but they seem to be quite high priced compared the the battery operated MW unit I had. Of course, Crane is usually above the general price on everything.

3064. Re: Feeding a 4 bay vertical folded dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-30 12:59:06 UTC
From: Bob Bob <bob3bob3@suddenlink.net>
Message-ID: <r51344-sd3.ln1@p400bob.personal.cox.net>
Source record: 48787

There are quite a few possibilities

The first that comes to mind is that 300 ohm ribbon feed from all 4 antennas joined at one point will give you 75 ohms. The ribbons should be the same length.

You can also use a lower Z line in odd multiples of 1/4 wave to translate the Z down to a lower value. This is commonly called a Q section and is worth getting your head into! (you can also translate up in Z)

You will find that with mast coupling issues the antenna feed Z will probably be lower than 300 ohms anyway. If for example it gets to 200 ohms a tuned half wave of 300 ohm ribbon on each will translate the same impedance back to where you combine them. You would then get 50 ohms.

Coaxially you could make a 4:1 balun from 75 or 50 ohm coax. This is a nice way of feeding 200/300 ohm antennas from coax.

I think in my case I would be concerned what coax/ribbon/joiners/T's etc I had available for feeding the thing, then work out how to use them..

Cheers Bob

I personally know of very good 2 way radio techs - one who won't go for a ham license because of the code - the other has acquired his NO-Code Tech, but won't go any higher because he "doesn't" want to fool with the code. So, Code "may" be keeping out some otherwise good operators. CW alone - isn't "dumbing" down - ham. It's the "STUPID MANUALS". With them, you don't "need" electronics, just the ability to learn a few "one liner" answers. Almost amounts to a mouse in a maze smelling cheese to direct it. PUT SOME TEETH back into the "THEORY". Some of the bozos I've met - can't tell the difference from a fuse and a resistor. That is pathetic.

If you "choose" "just" to BS - CB is the way - and it too "can" be a good hobby, if you don't have to contend with a lot of the same CRAP - of everyone splattering, constantly saying Audio, keying up just to piss people off, and so on. IF you choose to "LEARN" - Ham "can" be the way. But then again, even at this point, I know some CBers who know more than many No Coders - or even Extras for that matter. There "are" some "serious" CBers out there who "get into" their equipment - knowledge wise. They have a "desire" to learn. There again, they won't go ham BECAUSE of the code. It is a two sided coin - but regardless - both CB AND HAM - have a lot of "nice"

folks and a lot of idiots - who - "could" be better operators if they tried. These Ham tests - do "not" test the "psychological" make up of people.

Code is ok - but it's not the salvation of the world - and certainly not the Ham hobby.

Still again - SC has "YET" to show proof of a license to back up his claims. People need to "ignore" him and move on.

Are you a "Pro-Code" person? If so, then how is it that you can be so with
such poor spelling skills?

If you are an example of what a "Pro-Code" person is, then I don't think
that HAM can really be "dumbed" down any further.

Ron

>> radio get dumbed down again.

------------ REPLY FOLLOWS ------------

People have only so much time and energy to spend on ham radio or
anything else. Spending hours on CW is truly dumb when they could be
spent on aspects of the hobby that are really important.

Bill, W6WRT

Knowing how to operate and apply EZNEC is a magnitude
more useful to me than Morse Code.

Ron, Morkie is the No-Code camp's worst enemy...He's one of "them".

Morkie (Mark Morgan, KB9RQZ) claims to have three college degrees, is allegedly now a geologist, and claims to have been "colonel" in the US Army Chemical Corps. He's the only multi-degreed professional that seems to be so incompetent as to be unable to employ spellchecking software, however.

The funny thing about his latter claim was that he (a) alleged to have been "drafted", (b) would have only bee SEVEN years old as the last conscriptee was being mustered out in the 70's, and (c) brandishes a sexual perversity that would get ANY officer's security clearance pulled, let alone play with NBC / CBR items.

He also claims to be a Jewish Pagan, whatever those are supposed to be, and has apparently "married" a male person while in Israel, which I find hard to believe...Not that he'd "marry" a man, but that the government of Israel would allow such things to occur in the Holy Land.

He's trashed every newsgroup he's come into contact with and has actually searched out newsgroups in order to cross post items in a lame attempt to intimidate those who he'd like to see go away since they make it a habit of busting him for his lying and tales.

So...Basically you're right when you say it can't get much "dumber" than what it is...He passed the writtens...perhaps. The jury's out on whether or not he was able to find a corruptable VE team to pass him after he passed them an undetermined quantity of Jacksons or Franklins.....

In any case...caveat emptor when it comes to dealing with him. I do it because I'm already in a high stress job and he's cheap entertainment.

If you are NOT SC, you are his brother... indeed the
glitch/mis-configuration/error or settings which have been introduced
into your news reader/poster is a dead giveaway!

Perhaps your "high stress" job leads you to commit such mistakes? You
really should look into getting some help with that "little problem" of
yours, they have done wonders with new medications, yanno? <grin>

JS

3074. what are you using for dipole supports

Hi
I been looking for the tv push masts that I used to use for supporting my dipoles when I was younger. I used to get the fifty foot one stick a ten foot top section and guy for a decent 80 meter suport system.I can find anything that is above thirty feet with the loss of tv antennas to direct and cable . Any sources or other good ideas for this. I really do not want to buy a tower for this espically as I had used several for different antennas. Maybe someone has done some groundwork on using steel or aluminium tubing? Thanks

IIRC -- without running down to the ham shack and diggng through my old copies -- some ARRL Handbook (and/or Antenna Handbook) editions back then had a complete project description for the whole shee-bang: folded dipoles, matching/phasing harness, mounting technique(s), etc.

Available on eznec.com, I have used EZNEC in
combination with SIMPFEED.ZIP to design phased
systems that worked well.

>just how stupid it was to "hero worship" such a trivial ability.

Such hero worship is over a half century LATE. But, some have
had their thinking conditioned by continuous propaganda from
a certain membership organization for just as long. Their brains
have been thoroughly washed and they found themselves hung out
to dry in the yard of ignorance and apathy of a time gone by.

>However, for one such as you, un-remarkable in all other ways type of
>guy, no great IQ, no other real skills or abilities, a general inability
>to get along in the general society, etc... for you, this was a way of

He can't quit now. Like Robeson, he's already dug his way too
deep into his own egotistical underworld, has NOTHING to support
his conception beyond the Archaid Radiotelegraphy Society (ARS)
propaganda that is over a half century out of date.

>Good luck...

I cannot agree on that...for, like all egotistical bigots, he
insists that he is the "model" for all to emulate. Ignorance
of the rest of the radio world is no excuse. Rather, I wish
him all the bad luck possible. :-(

>P.S. I am really not psychic--but you already knew that... It is just
>that such small intellect as you display is simple to define... but you
>knew that--already. You are simply trapped by the particular mental
>disorder which plagues you, your world is small and therefore you expect

>limited performance, a small performance, a vile performance, but
>still--it is yours, and it tells a much larger picture about you--how
>much better it would be if performed for people who actually cared...

Absolutely NO psychic abilities needed to see his "act" and
judge this meanderthal of morse. If he were really on stage
he would be booed off without any audience hesitation. Exit
stage left...hastily.

The odd part of these forums is that they do NOT exit. These
sociopathic bigots enjoy their own virtual worlds too well to
leave. Separated by time, distance, and anonymity possible
in here, they fear nothing and operate with impunity. They
love only themselves and their words, the "getting even" with
all others who have given them frustrations elsewhere. They
need the tarnkappen of their own-tailored invisible clothes
of grandeur. If there be pity for them it would be for their
own naked ignorance.

LA

3081. Re: FM Transmitter for CD Players?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-11-30 20:37:30 UTC
From: Alan WA4SCA <APBIDDLE@UNITED.NET>
Message-ID: <9ufum25j5l0g936i4m21jvrpel2p6vflk2@4ax.com>
Source record: 48804

Take a look at their "orphans" page. The FM transmitters are $10
cheaper there, but with the same guarantee. Over the years I have
gotten two orphan items. Both were indistinguishable from the regular
items, right down to the package..

Still not cheap, but perhaps a small help. Much like Brookstones, if
you can find it somewhere else, it will always be cheaper. However,
C. Crane and Brookstones often get the quality stuff sooner.

Are you referring to masts that come in 10' sections and can be
assembled together, one inside another? If this is what you are
wanting your Ace or True value hardware have them or can order them.
Mine cost me 2 weeks ago $15.99 each plus sales tax. They fit one
inside another to whatever height you want.

Also, if you have a Lowes Home Center nearby, they do tend to carry those Wineguard type telescoping TV antenna masts, too. ... at least to the 40' variety. Whether or not you'd find one in stock or have to order is another story...

Hi Mike, Since an 80 meter dipole needs 130' of space, can you find a high tree for one support? The push-up masts that are currently available are in the 30' range, and will not get you up 60'.
Are you sure you need a full size dipole up 60'? Consider an inverted vee up 60' at apex, needs one support. Ends drooping down 30-20'. I have used this configuration many times, works well.
QST published an article on a tower based on 2 X 4 lumber, and I seem to remember articles on irragation piping used for supports. Good Luck.

Their transmitter may cost more, but is a cut above the 2 or 3 others I have owned previously. It's also one of the only ones I've purchased that actually seems to put out something in the range of legal power and deviation, as opposed to the Radio Shack ones (no longer on the market) that will go REAL wide. It's also nice to have a fully synthed unit as opposed to many that just are on a 4 or so freqs and that's all.

> Bingo!!!!!

I'm happy you two lazy ass Lids found each other, when ya getting
married?

I suggest you two, plus Markie, Opus and stay out of this thread. It's
only for people like me that want to protect and preserve the quality &
integrity of the amateur radio service. People like you, John Smith,
Opus, Lenny and Markie want to destroy it because you believe people
shouldn't have to learn anything or be good at anything to be a ham radio
operator.

SC

Been there, done that!

I just looked at the license requirements as likened to the
responsibility of owning a dog. If you are going to own a dog, you are
going to pick up some poop! Code is much the same to owning a station,
as poop is to owning a dog, it's almost a 1:1 correlation.
...yawn...

Yeah, but I have high speed. I can afford it. You, well now I understand why
you like CW so much. It goes well with the spark gap that you use...of
course most hams have real equipment, but you can only use what you can
kludge together with old beer cans and salvaged copper wire.

another take on modified antennas ...

I have a magmount dual-bander on the roof of my mini van. It terminates in a BNC for use on an HT.

The stock AM/FM car radio antenna went bad with an open shield and it was picking up lots of noise. I pulled the radio far enough out of the dash to unplug the bad antenna. I plugged in a Moto-to-BNC adapter and dropped a short piece a piece of RG-58 down to where I could mate it with the mag mount's cable connector. Works great. Quick disconnect BNC lets me go back and forth as necessary.

BONUS: For our regular trips across the desert, I have an extra-long whip element that I substitute in the magmount base. I lose the match at 440 but it still works like a champ for 2M or AM/FM, my choice.

I have not played with diplexing as swapping connectors seems too easy. Yeah, a switch maybe ... someday.

I'm about to refuse delivery of the kit when it arrives, and I've ordered
the orphan. I think this should be a very helpful device. I cannot get a
distant station in SF, KGO, because I need a device in the bedroom where I
have the C. Crane radio that interferes with KGO. When I put it 30' away,
reception is fine. So I'll hook up the FM xmitter to the Crane and pick it
up on another radio in the bedroom. This will also help in an out building
where reception isn't so hot for a number of FM/AM stations.

3106. Mounting antennas atop rowhomes?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-01 04:42:28 UTC
From: "E. Recio" <e_recio_polywog_org_FirstTwo_at_SecondTwo@foobar.com>
Message-ID: <16c19$456fb2b6$4503f904$7006@msgid.meganewsservers.com>
Source record: 48829

I want to get a simple omnidirectional antenna in the air. Part of the issue is that I have heard hairy stories about attaching the antennas to the chimney. Problem is that I live in a rowhome. The front and rear is stucco. Really the only thing to attach it to is the chimney...

I can drill into the stucco in the rear of the house, I guess... but would like to get some ideas?

I am thinking something for 440/1.2G. But that's just the beginning (since it's the smallest, I am figuring). Additionally, whatever the mechanics of what I put up, it - the mounts - should be able to support larger antennas for the lower bands for the future.

Any ideas would be helpful. I kinda want to do this right to save myself pains of structural damage to the house 10 years down the road.

SC:

Sometimes I am convinced that you are an excellent "satire comedian." Other times, you have me convinced you are for real. Sometimes you have me busting a gut and laughing until tears come, other times you yank my heart-stings in pity.

Take this last post of your, it can be viewed as tongue-in-cheek satire, or, it can be viewed as insane rant.

Certainly you cannot place much importance on CW. Amateurs have a real purpose, to expand radio on ALL frontiers. Help in the community, help in educating the youth in radio, help in disasters, help in developing techniques, equip., theory development, etc. (the list really goes on-and-on here)

Probably the least important aspects of all this is rag chewing, contesting, favoritism of individuals and groups, etc. They are fun for some and amateur radio has a place for these activities, but these are self-serving and we must be careful least amateurs on a whole end up being judged on such self-serving behaviors. However, when we are taking from amateur radio for our own personal goals, likes and entertainment we are NOT giving. Or, put simply, I can easily imagine Einstein, Tesla, De Forest, Bell, etc. having a great interest in radio, however, I am in doubt as to them getting excited about having to learn morse to obtain the license.

So, when you go crying "the sky is falling" over amateur radio progressing and dropping an ancient tradition of morse testing, how can any logical mind view you as NOT being self-serving, how can anyone take you seriously at all? Are you a con man attempting to sell us the idea that you really see great benefit in CW? That CW is a major part of radio in 2006? Come on man, anyone crying such nonsense is going to be called on those cons schemes immediately.

You see CW as being a real barrier, something that many who desperately want to become amateurs will avoid and by so avoiding fail to obtain an amateur license. Certainly you cannot really believe that; you can see how people would view you as deranged if you held such views, can't you?

If someone really wants an amateur license, it they are so devoted to hero worship of amateurs as your were--they will end up with that license in their back pocket--even some uneducated and mentally challenged person from the back swamps of DumbBuck Egypt can learn to tap that code if he/she is driven.

I think as a young man, you viewed amateurs in some form of hero worship. I think you viewed them as larger than life. I am afraid that once you obtained your license, these fantasies did not fade. Indeed, you wove these fantasies into your ego and your ego became dependent on your amateur license hanging on your wall. You recognized that if a very large number of people had amateur licenses (say the same number who hold fishing licenses or drivers licenses or contracting licenses, etc.) your feeling of being "special" would go away. So, you began to plot. You began to find ways you felt would stop people from getting licenses and get behind those ideas and push them and sell them. You certainly knew there were other such individuals as yourself out there and they would come to your aid. Indeed, I do not even think you were the one to come up with the original idea, I think that would have been beyond you. Someone else came up with the idea, you just jumped on his/her bandwagon.

So, now we arrive here. And, you are indeed correct, CW does make some shy away from amateur radio. The reward of having an amateur license is just not big enough for them to learn a set of dits and dahs to send messages with, frankly, I see Einstein never bothered. I guess you look at this as a "winning" situation, I do not. I look at it as a evil self-centered plan which you and others are engaged in to limit amateur radio, and it just kind-of-got-that-way because no one has taken you to task.

I know of no good reasons to maintain any CW requirement in amateur testing. Even learning it for historical reasons does not justify the expenditure of time and effort it requires just to purchase a radio, buy an antenna and grab up a mic (and that is exactly what the large majority of amateurs are today, code tapping appliance users.)

In all your rants I see no real reasons for maintaining the CW requirement. In fact, when you are hard pressed and under attack, you admit to having your self-centered self at the core of you manipulations.

If you think I hate you, I do not. If you think I see you as the most evil person I have ever conversed with, I do not--I have some neighbors much worse. I just don't understand you. And, why that is, is because no one here is attempting to "win" by eliminating morse. We are attempting to win by making amateur radio enticing enough to fill our ranks with new bright minds, something YOU SHOULD place much more importance on. Indeed, CW pales in comparison when viewed side-by-side.

Let me leave you with one important "vision" to dwell upon. Next time you are a social event, a cocktail party, a civic function, etc. and you find someone, or some group who is really, really impressed with you

being an amateur radio operator--then, right at that time, take a really, really good look at those people who are so all impressed and tell me if it really matters that you impress "those people?" If you say yes, you and I don't even live in the same universe.

Regards,
JS

Interesting. Does speach apply to CW? After all, it is a non-voice form of operation.

>> If so, then how is it that you can be so with

I am a no-code op. Removing the requirement for CW neither dumbs down the HAM service, nor makes it more intelligent. CW is a niche form of operation anymore. Some people enjoy it for reasons that I cannot personally fathom, but what the heck, if its their thing then let them have at it. More power to them. CW is no longer the main mode of operation used anywhere in the world. Phone is. CW has no "practical" use any longer, it is used for entertainment only. Again, more power to those who choose to do it. Removing the 5wpm requirement for more advanced licensing only makes sense. No one requires anyone to know PSK31 or RTTY now do they? The FCC does not add that as a specific element of the testing process because it is a "mode" of operation, no more or less than CW is. Knowing and being able to operate CW does not make one more of a man, more of a woman, smarter, taller, slimmer, or better looking. Its just another mode of operation, one that is going into retirement slowly and painfully. Why not just let those who enjoy it, do so, and let the rest of us get on with expanding the hobby into new areas that technology make available to us. Why force us to regress 30 years instead of allowing those who enjoy CW to learn and participate in the revolution that technology is providing for the Amateur Radio Service?

Ron

sure it does

which is ilrelavant to the fact that the ARS would be better off if it
were banned

staing that the ARS would be better if CW USE were banned is not the
same as calling for it to be to be

that you choose imply it is is indicative of your lack of skill with
english or in your lack of belief in the free speech rights of all

the facts you object and insinate that I lack the free speech to state
my opinion is IMO indicative that you don't truely believe in free
speech etc for yourself

He isn't driving "me" away from ham. People like him - come and go every day
in my life. I look past them.
I just wish "others" in "here" did that! His posts are ruining "these"
newsgroups.

And for what it is worth, I've been an Extra for about 12 years now. No one
yet - knows what SC is/was! He's never said, that "I" know of. Though I have
my "Extra" - I kept my "Novice" call sign.

3114. Does icom w32e work well with optional antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-01 08:15:11 UTC
From: iche <ichejohndoe@yahoo.com.tw>
Message-ID: <1164960911.640540.186720@l12g2000cwl.googlegroups.com>
Source record: 48838

hi there:
I bought a w32e transceiver the other days, the receiving sensivity is perfect when I used it with the orginal bnc short antenna, but when I changed it with another longer antenna(M-type) + 5 meters cable , the receiving sensivity drops down dramatically. The situation is : the signal indicator booms up almost to full scale, but the content of the signal is poorly readable, I've checked the optional long antenna and the cable with SX-400, they are all OK, then I send the w32e to be checked by the technician, it is OK too, so I begin to wonder :Does icom w32e work well with optional antenna? Are there anyone have the same problem as me ? or can any part go wrong ?

Regards.
desperately one

Nope.

The IP Address and servers are complete proof that I do NOT share
any annonymous character's "address".

> Perhaps your "high stress" job leads you to commit such mistakes? You
> really should look into getting some help with that "little problem" of

What is interesting is for every post SC makes, you whining crybabies
make 10!

As for driving people away, Ham Radio needs more QUALITY not QUANTITY!

Does it have a roof you can (or are willing to) make holes in?

While I don't live in a rowhouse, I've had a small TV tripod on the
roof which has been supporting an R5 vertical for years.

Hi:

Does the signal indicator go way up even when there is no signal? If it does
you have either a high noise level or a very strong signal that is near by
and is overloading the front end electronics in your radio. This strong
signal overload is very common in areas where there are lots of
transmitters. The short antenna doesn't pick up the offending signal but
when you go to the bigger signal it picks up more of the offending signal
and overloads your radio.

To anyone with even an elementary understanding of anonymous proxies, anonymous remailers, zombie backdoors, etc., the ability to change ones IP address and header details is simplistic, indeed, with little time spent anyone can appear to be "coming" from anywhere in the world.

You waste my time. Worse, you think us all idiots here. You remind me of the "street smart" prosecutors and defense attorneys who stack jurys with members of little or no technical knowledge and then call in "expert witnesses" and propose arguments of technical details to boggle their minds.

You have only proven that you, yourself are either ignorant to such technical details, or else you are indeed street smart, I favor the latter in this case (however, if you in the dark about such things, 15 minutes on google will enlighten you.)

Steve I can easily fake a set of header for any location where I had
interenet access in the past

I lack the knowledge of how to generate new one but I know it is can
be done

you are therefore lying when you claim thae fact you succeeded in
comiting forgery is proof you are not SC

it is merely proof you are a forger

"Entertained?" :-) Hardly. I took off for three weeks to
rid my environment of all the sociopathic meanderthals
that inhabit this Din of Inequity.

I come back and its like the ghost of Claude Rain's character
in the movie "Casablanca" has been whispering to me..."all the
usual suspects" have been rounded up and imprisoned in here. :-)

It's truly remarkable to see this totally-retro group of
frustrated "radio operators" thinking the radio world hasn't
changed for 60-70 years...all of them thinking they "know
what is right" for a radio hobby...because what They do is
absolutely the Best and all should emulate what They do.

Where is Paul Schleck these days? Here it is 1 December and
his "threatening" troika of "moderators" haven't yet appeared.
I wonder if he has been appointed to a new cabinet post? You
know, the "Department of Hamland Security"... :-)

Holiday regards,
LA

3132. loop vs dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-01 21:48:40 UTC
From: John Doe <hgorden@adelphia.net>
Message-ID: <ubadncBWvNqzPu3YnZ2dnUVZ_tSdnZ2d@adelphia.com>
Source record: 48856

I live in a antenna restricted community!

I have put up a somewhat stealth antenna. 13ga - stranded copper - blk jacket!
It is a 540 ft loop = 180 ft virtually lays on the roof and the remainder 360 ft is in my attic.
I feed this with 50 ft of RG58u at the center point (6 turns of the feedline - approx 8" dia is used as a RF choke) running down to a manual tuner.
The antenna in this configuration is about 1.1:1 to 1.5:1 across all the bands from 75m to 6m. I would like to operate on 160m, but the tuner doesn't cover that band, and when I try to go directly the SWR is extreme and we don't use it!

My questions are:
1] should I leave the antenna system alone as is? It works - but as a wire system has its limitations due to the clearance off the roof?
or
2] should I purchase another antenna tuner that covers 160m - 6m. and open the LQQP and make the antenna a single 540 ft piece of wire and ground the other side?
or
3] should I purchase another antenna tuner that covers 160 - 6m and try to make the long side similar to what ever wavelengths are equivalent to a Windom configuration?
or
4] should I just open the loop at the furthest end and make a huge dipole out of it?

Hi John, Since the antenna works on everything but 160m, I would
just leave it like it is. How do you know it won't tune on 160? 540'
loop is a lot of wire and may present manageable impedances to your
tuner. If you could get an antenna analyzer and check the impedance on
160m you may find your tuner will work. If your tuner won't, a simple
"L" network tuner should get you on 160 without much trouble.

The RG-58 going from the antenna to the tuner should be a short as
possible. The line plus the coil choke should not be over 10-15'.
This is per W2DU in "Reflections". If you need a longer run, try 300
ohm or 450 ohm twin lead.

When I lived in Chicago, my two story house was on a small lot, and the house were close together. So there was no room for anything except a vertical. The easiest way was for me to attach it to the chimney. My antenna was a Butternut HF6V that was around 30' long. I don't remember exactly how long. Anyway, I went to Radio Shack and got this kit for attaching to the chimney. It had two ratchet mechinisms that had straps attached. I put one on the chimney, just above the roof about 6". The other was put almost at the top. The straps went around the chimney sides and back in the ratchet and then you tightened it. Then you slipped the vertical in the two supports and tightened.

I had that vertical up in snow and ice storms and never had any problems. I couldn't have put beams up because they would have stuck over the property line and over my neighbor's roof, which wouldn't have gone over very well.

Anyway, that's one thing that worked.

That's my analogy too. I've always seen that operators and the bands are like owning a horse. You get some good operators that will do everything they can do to be good communicators that will work to improve on their knowledge, skills and are willing to help others be better operators too. Their efforts like a work horse carry ham radio to new places. (me)

But not everyone wants to be valuable to the service and a good operator. They are like turds stinking up the bands making them unpleasant and stagnant. They don't care to be skilled, or if anyone else is skilled and knows anything either. They prefer the smell of turd. They get a license and plop on the bands like a horse turd plops on the prairie.(you)

It is a 1:1 correlation.

I'm a firm believer in using humor and satire to try to make my point.
It's like cracking a walnut with a sledgehammer. Whether or not anyone
wants to accept or agree with me, I hope we can all still have a good
laugh.

> I know of no good reasons to maintain any CW requirement in amateur
> testing.

How about, Requiring it in order to be able to communicate with it?
That's a good reason and you're learning a skill. Keeping people like
Markie off HF doesn't sound too bad either.

The first time you hear 'AAAAAAUDIOOOOOOOOOOOO' or 'skipland skipland
skipland' in the middle of 20meters, you'll get a change of heart and will
want to beg forgiveness at the Church of Hiram. I heard it a couple times
and it made even the hairs on the back of my neck stand up and I was
already born again.

You think this is bad, you ain't seen bad. Just wait until the Lids take
over HF after CW is eliminated, then you'll be sorry.

That is, You'll be sorry unless you like what CB sounds like.

You really are a bitter ham. Lack of CW in the radio diet will do that to
you. Just look at all the hate on eleven meters. Those people are even
gunning each other down in shopping mall parking lots.

Interesting, but you cannot argue with decibels, and the yagi is more efficient that a dipole without reflector and director, at least at capturing signal.

However, while I can picture the reflector acting as a mirror (and to some extent, this can be "proven", make the reflector a sheet and see how much signal is radiated to the other side, away from the driven element.

But, that darn director has always bothered me, I see it acting more as a "magnifying glass to rf" than absorbing the signal and re-radiating it to the de, or absorbing the signal and coupling it to the de via magnetic or capactive means... one more bit of a puzzle which gives me visions of the ether (which some say is caused by evil spirits and/or the drugs I did in college (I don't think the beer hurt anything!))

But, with his calculator in hand, I know cecil will take this head on...

And to continue the theme -

Actually Art, yagis are usually better than 95% efficient.

Hi Art

OK, I dont understand. Perhaps I could begin to understand if I was
given the definition of efficiency we are using in this discussion. How do
you define efficiency?

Jerry

And, actually Art, and most important, you seem to have no comprehension about what is possible to realize with a yagi that is about a half wavelength. What you want to do takes yagis that are 10, 20 or more wavelengths. And very high above the ground.

Reality is a nasty thing.

So the increase in reactive impedances radiation efficiency goes up?

Oh come on John, Llewellyn states the rear adds to forward radiation
and you come along with similar junk. A vector to the rear where there
is an detuned element which some how
over turns the idea of energy can't be created or destroyed ? I suppose
Roy will come up with some trash that because the reflector is reactive
it overcomes the vector that created it!

>
> But, that darn director has always bothered me, I see it acting more as
> a "magnifying glass to rf" than absorbing the signal and re-radiating it

Come on John if it is detuned from the frequency of use it can;'t be
reradiating everything
remember the hint I gave in the posting

> to the de, or absorbing the signal and coupling it to the de via
> magnetic or capactive means...
Oh John you have done it again if you are going to revolve
your position around coupling then losses will mount up
even more. It really isnt a puzzle unless you listen to
comments from experts who only read about Yagi's
and shut everything else out or are just looking for an
opportunity to snipe or emmulate snow code.

one more bit of a puzzle which gives me

I thought ether was something that did not posses its own energy
support
only a mediam for energy to pass thru, but we could change the
subject to that I suppose

Not a reasonable answer, could be speculation like some of the comments
I get from experts. The yagi is not totally efficient in changing the
time changing field to a radiative field
because it has detuned elements contrary to what Roy states that a
reflector aids the forward lobe.......that is trash talk but many of
the so called experts are following like lemmons

Not a reasonable answer, could be speculation like some of the comments
I get from experts. The yagi is not totally efficient in changing the
time changing field to a radiative field
because it has detuned elements contrary to what Roy states that a
reflector aids the forward lobe.......that is trash talk but many of
the so called experts are following like lemmons

So why is it then, that Roy and several dozen others here have made good livings, written respected books, and designed antenna systems that defined how good it can get? And all you have done is call them names?

Sounds like the "so called experts" are a lot effing smarter than you.

All you have done is throw stones, which is what you accuse all of us of, by the way. And you haven't given a microgram of proof that what you believe is true.

Hi Jerry perhaps I am wrong that there ARE people who want to talk
antennas
We went thru this some time ago and I was referring to efficiency of
the yagi antenna
with respect to the radiation field where much is reflected to areas of
no concern.
Others did not like this and said efficiency referred to is one of the
radiation facets of a radiating array and the yagi is efficient and
then the sniping statrted and the newsgroup went down hill as others
joined to emulate and perpetuate abrasive non antenna related
subjects. I just popped back to see if the group wanted to change back
to antenna talk
and posted the term efficiency of the yagi in terms of radiation which
everybody was
auguing about. Well things haven't changed they still just want to
throw stones and more will join in as the thread goes on., Ill stick it
out for an hour or so and then move on again.
Cant wait for somebody to compare with free space stuff to add to the
confusion, I know it will come

There you go Tom still giving comments but no substance. Pretty simple
accept that a yagi
is not the best thing since sliced bread starting with the use of
detuned elements.
If you do not understand what detuning elements do then you can have
nothing reasonable to offer so don't blame me for that. If you have a
salient staement I'll listen because I started the thread. If you want
to change things then start your own thread to get them talking about
it. Boy.....posts are coming out of the woodwork, where has everybody
been?

Tom if you want to align yourself who say they don't understand that is
fine with me.

Do you have anything to say about radiation efficiency of a yagi which
is what the posting is about you mentioned something about 95 efficient
which you got from some where you could describe why and how 5% of the
input anergy is lost or were you just guessing?
Start a new thread if you like and I will go to bed as I am going
nowhere with this and I am not anxious to stay when profanitys break
out and it is heading that way

Bill prove me wrong thats all you have to do prove me wrong
Its a simple statement detuned elements create inefficiency
Avoid it like a plague you say, it is to late in your life to think
about getting an education You have presented nothing of value
to the question, absolutely nothing. I suggest you continue to
be a lemming and follow the others. Doesnt it worry you
that you have placed yourself out on a limb by preceeding
experts comments instead of waiting so you can follow ?
Seems like the antenna group is still happy with their fellow
associates in the group so pick up some more stones say
some swear words and impress
the others.
See you maybe in a couple of weeks when I may drop back in.

so save some of those projectiles!

No others that I know of.. Radio Shack has one, but it's low powered, if I remember it. The Ramsey went about 100 feet off a legal wire (30 inches, I think) and the RS only about 25 feet. I am in a metropolitan area, which is a disadvantage to these little units -- hard as heck to find a clear spot! Then too, receiver AFC pulls off to something else if you suffer a fade.

Jerry:

You make that sound like such a simple question.

Antenna efficiency is a complicated and often misused figure.

All antennas suffer from losses. A simple horn antenna for example will
not be as efficient as a perfect aperture of the same size because of
phase offset. The real efficiency of an antenna combines impedance match
with other factors such as aperture and radiation efficiency to give the
overall radiated signal for a given input. The best and mostwidely used
expression of this efficiency is to combine overall efficiency with
directivity (of the antenna) and express the efficiency times
directivity as gain.

The above is NOT mine, but taken from the web...
http://www.tmcdesign.com/antenna%20catalog%202001%20cd/Helpful%20Antenna%20Information.htm

So, we need to know if we are discussing antenna efficiency, or
radiation efficiency, or the skin effect as related to the ether
efficiency, etc. <grin>

Good that you are asking him!

Regards,
JS

Hi John

It really *is* a simple question. Again, how is Efficienct being defined
for this investigation?? As you have written, that question has to be
answered by Art, the original poster, ?doesnt it?

I was a little embarrassed because that "definition" of gain in the referenced site was really difficult for me to understand. I really admire you guys who understand phrases like "phase offset" as related to efficiency.

Jerry

Of course you have to remember that as you get older those things can
be a bear to climb. <:-)) and then stay up there for the whole
afternoon. OTOH I'd like to have at least a couple elements on 40.
I'd give up the 144 and 440 arrays to do that. Not sure how close I
could get the 40 to the tribander with the 6-meter yagi about 12 feet
above that.

Oh! Lost the 160 sloper due to a shedding will tree yesterday during
the storm. I have to go all the way to the top to fix that.

There is a CAUTION for chimney mounted antennas! The normal brick chimney is design and built for vertical loads [concrete and bricks]. It is not designed for any torque loads [twist and/or bends].

Small tv antennas seem to be OK. I would be cautious with larger Ham antennas.

Given the freezing rain yesterday it will be a while before I climb the
towers..
The bolt sheared on the 4el-40 mounting in that wind a couple days ago
and the beam is tipped up again... Looks like it has to come down
<sigh>
You are right, as you get older this gets to be less and less like
fun...

Comparison: RoomCap with EH-Antenna

The EH-antenna is offered as a compact, efficient short antenna.
The user reports about this antenna are very varying, from
enthusiastic
to unusable.
Therefore, I was interested since long time to perform a comparison
test
of the RoomCap with this antenna.

On Nov 30, 2006 we could do that.
Andy, HB9DWF is owner of this antenna, and he was willing to
perform
a field test.
We installed both antennas in a free camp and tested exhaustively
on 160m.

Comparing antenna: EH Venus from Arno (Italy, WIMO Germany)
Length = 2.5m, Diameter = 8cm /
12.5cm, Weight = 4.9 Kg
Test antenna : RoomCap 160m, radiator length = 3m,
Diameter = 7,5cm
with top capacity

Both antennas were installed with about 30m separation, at a height of 1.5m
above ground, and connected via decoupled coax cable and coax AB switch to
the 100 W transceiver.

First, the SWR was checked:
It was found, that the EH antenna is very narrow, in contrast to the statement
of WIMO who says:
"due to the design the entire band can be used."
The acceptable bandwith of the antenna was found to be just 20 KHz (!)
with resonance at 1.860 MHz.
In contrast, the RoomCap can be used in the full band from 1.800 to 2.000
with a VSWR 1:1, without using a tuner.
This problem complicated the testing somewhat, as we had to ask the
remote stations to change the QRG to 1.860 to allow operation of
the EH antenna on its best operating frequency.

The comparison tests began at 20.00hrs with a duration of one hour and 20 minutes.
Until then we had 11 test contacts, and Andy said, that further QSOs
do no longer change the result. The result was clear.

In each contact the antennas were changed many times, and the remote
operators were asked to measure the signal difference.
All stations reported that the EH antenna is significantly weaker, and
they reported signal differences beween 2 to 4 S points.
The averaged signal difference was 3 S points.
Some stations were unable to measure the signal difference, as the
signal of the EH antenna was not readable.

The following stations participated in the comparing test QSOs:
F9EZ, I2BBJ, HB9ZY, F/HB9DHO, HB9BBM, HB9AGN, HB9COP,
HB9JMD, DL9FCP, DL1EFR, DB3MA.

Conclusion:
The test showed, that it is possible to make contacts with the EH antenna,
however the signal strength in comparison to the RoomCap antenna is
about 3 S points weaker.
(18 db correspond to a power relation of 1:63).
This "good result" is obtained only, if the antenna is operated within
20 KHz of the resonant frequency. If the antenna is used outside this

frequency range, an additional signal loss of 1 S point and more is
to
be expected ...

The above statement does not agree with the measured patterns and performance results of Yagi antennas.

A well-designed, 6-element Yagi has a peak gain of at least 10 dBi, which means that it radiates about 6.3 times more power in that direction than if the same input power was radiated by a reference 1/2-wave dipole, and measured in its direction of maximum gain.

For those who wish to actually learn and not just insult each other, get a calculator, learn how to calculate Cosine Theta <a trivial math problem that any 9th grader can be taught in 5 minutes flat>, get a BIG piece of paper <reason to come>, and actually calculate the shape and vector length of the lobes of a two element Yagi-Uda antenna... Do the calculation in both the horizonal and vertical planes... From that you can calculate the volume of each lobe, which is proportional to the percentage of power in each lobe... From that number you can very simply calculate what percentage went into the lobes you prefer and what went in the lobes you don't prefer...

Now, the reason for the BIG piece of paper... The antenna patterns you see on the screen with EZNEC, or in the antenna handbooks, are logarithmic, not linear <and there are flavors to them, ARRL, linear logarithmic, modified logarithmic>... So, the patterns are distorted... Why is that? Because if they were linear and the front lobe and the rear lobe are to the same scale the front lobe will take up the entire length of the screen/paper and the rear lobe will need a magnifying glass to be seen... A rear lobe that is 20dB down from the front lobe is down by the power ratio of 100... So, if your forward lobe calculates out to be 10 inches long, the rear lobe will be be 1/10 of an inch.... I'll let you figure out the size of a lobe that is 30dB down (get out your microscope)

For those who want to review do a search on Joseph Reisert, who has published numerous writings on antennas and patterns... There many are others also, but Joe is published on the web, and very readable...

cheers ... denny / k8do

What kind of efficiency? antenna? beam? aperture?
overall? conduction-dielectric?

Balanis defines overall antenna efficiency as the
product of:

1. reflection (mismatch) efficiency
2. conduction efficiency
3. dielectric efficiency

He gives the conduction-dielectric efficiency as:

Rr/(RL + Rr)

where Rr is the radiation resistance and
RL is the (conduction + dielectric) losses

He gives beam efficiency as:

(Beam cone power)/(Total radiated power)

He also says for a 1-dimensional aperture as a
function of taper: "The aperture efficiency is
a maximum with no taper, while the beam efficiency
is a maximum with full taper."

The problem here is not math, it's English. You are calculating gain
and/or directivity, not efficiency.

New to restoring chassis's on vacuum tube radios, and want to know from antenna experts what better solution is there than just a long wire. Most my radios are AM/SW, and would like something simple to attach to the antenna screw on the back, and have full range reception. I've heard the term 1/2 wave dipole with a balanced lead-in, but don't know what that would look like. Thanks

Cecil:

I think caution is best used. Reminds me of the three blind men who went to see the elephant, one grabbed the trunk, one a leg, the other a tail... and you know how the story goes from there.

I think there is confusion between the radiated power, only allowing for resistance/dielectric losses; as opposed to why it is desirable to allow some loss introduced by other elements because the net gain of "focusing" the antenna is a benefit to you is the major crux of this whole discussion. But then, I am not even sure of that, completely!

I suppose the most "efficient" antenna, with only taking into consideration the power delivered to the antenna though the feed line and actually arriving at the feed point to the antenna as the "antennas input power" in relation to the actual "power radiated" (or delivered to the ether) is what Art is looking at. And, in this one regard, I would suppose a full wave dipole with large dia conductors (to allow for skin effect), silver coated conductors and glass insulators would be the most "efficient antenna" (and allowing for a "perfect match" setup being installed.)

But, where is that power going into the lobes may not make it the most desirable antenna!

In the yagi, because the reflector and director are so close to the de in terms of wavelength do introduce some trivial? (depends again on perspective) losses here.

And, here comes the fairies and the pinhead.

JS

for receiving, the common low dipole with whatever size legs you can make
works just fine. which is easiest to use depends on they type of antenna
connector on your radio, if it has 2 terminals then a dipole with twinlead
or coax plus a balun would probably be easiest. if it is only a single
terminal then just go with a single random wire. note that you can run the
random wire right from the back of the radio, but because it will pick up rf
noise from anything it goes near you might want to use coax to at least get
the antenna away from rf noise makers like tv's and computers first.

Of course, I always think of the parabolic reflector antenna as the
"most efficient!"

I have never seen one constructed for 160m (strange huh?); but when you
get into ghz, why would you ever use anything else? (well, unless you

wanted to chat off to someone on the side or back.)

After years of resisting I'm ready for a moderated antenna group. I've
used my kill filter more times in the last three months than I've ever
done in the previous ten years.

I, for one, am sick and tired of the foul-mouth off topic postings
and, if that requires a moderated group to get rid of them it would be
a very small price to pay.

Hi Art

As I read it, the efficiency (in percentage) we are using for this
discussion is Power Out divided by Power In, if the "objective" is to
radiate power. Or, correct me if I misread.

Jerry

3213. Re: Yagi efficiency

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-02 18:51:13 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1165083641.970759.301830@80g2000cwy.googlegroups.com>
Source record: 48687

Very good points John, the subject first started out some time ago when
I stated that thge yagi array was really an in efficient way of
providing communication point to poit because it can be seen that the
radiation field points all over the place. The comments first came back
that little energy was exposed outside the main lobe which then people
stated it wasn't a measure of yagiefficiency bringing gain and a lot of
miscellaneous stuff until they got to the point that the yagi was
efficient and the real efficiency revolves around radiation itself.
Then sniping started and I took off for a while.
When I came back I modified the question
to what people thought the question should be because that was what
they had an answer for but again they got screwed up because the
subject still remaines the yagi with respect to radiation fields
knowing full well that radiation cancellation enters heavily when
determining final radiation fields which is why one should not bring in
gain to the picture. So cutting out the clutter of environment and
dielectrics used etc the question is phrased around the transfer
arrangement that the Yagi uses to translate a electrical power input
for the production of a time varying field which is the most simple
basic aproach since we are dealing only with the eIR equation in
obtaining the energy change over efficiency with respect to the Yagi
antenna alone.No nead to show off your perceived knowelenge about
antennas or to change the subject so that one doesn't have to show
their ignorance of factors outside of Ohms law which is all one needs
to know. But sadly in this newsgroup people get upset if one doesn't
know the answer to the question prefer to divert things to a question
that they do know the answer to and do this by questioning the
intelligence of the poster first before their own intelligence becomes
the question. From the very beginning I gave the hint where it can be
reasoned out without a lot of uninportant clutter but unfortunately all
ignored it as possible drivel. Is it any wonder that antenna talk and
aspiring amateurs shy away from this newsgroup and where it attracts a
different sort of clientele in line with present day activities? My
goodness a dipole is a basic element in any antenna array with respect
to effiency but an arrays efficiency is based on the additions to the
driven dipole of other elements used to produce the near field to
produce perceived benefits which is outside of this question. I realise
that all hams do not have to be electrical engineers but it does seem
the purpose of some is to complicate things beyond the comprehension of
those who we wish to have in the fraternity in an attempt to elevate
them selves in fraternity fashion. Oh well I can't change the world!
The yagi has held its own since the 1920 so it must be sacrelidge to
examine it furthur to expose more efficient means of producing near
fields. For myself I have written around a new form to be published by

the PTO and was intending to discuss its merits with this group first
but I now realise that information iand knoweledge is not what is sort
after, only targets to throw stones at.

I doubt many would disagree with you. I think what you are actually desiring is "robo-moderation." In which posted text is sent to the moderator and there is examined automatically, by software app., and either passed or trashed. In such a method posts bearing foul language, CW terms, policy terms, etc. would automatically be trashed.

A moderator "hand moderating" posts is more than anyone should be required to do.

Here are some facts about moderation, robo-moderation is described with a link on the page:
http://www.swcp.com/~dmckeon/mod-faq.html

At least I'm a ham. That can't be said of you.
```

> Lack of CW in the radio diet will do that to
> you.

Nope, being accused of molesting Boy Scouts did it for me.

Everything that K4YZ/KTN4GN says is suspect and needs to be
scrutinized.

For example, his Civil Air Patrol FOUO letter that was published in the
Nov 2006 issue of PopComm completely contradicts his QRZ.COM/K4YZ offer
to confirm his CAP communications.

That is what this thread is about... if you'd care to stay on topic.

> Just look at all the hate on eleven meters.

I wouldn't know, but there's no need to look there. The hate is
already on RRAP, and K4YZ fosters most of it. When this group becomes
moderated, I expect K4YZ to be banned. He'll have to hang out on the
Nurse or CAP yahoo groups of his own creation and moderation.

> Those people are even
> gunning each other down in shopping mall parking lots.
>
> SC

What a coincidence. K4YZ has offered to "meet" several hams at the
Dayton Hamfest, and there's a lot of hamfest parking at the shopping
mall.

Art:

Antennas are simply, I mean let's face it, they are just a bunch of metal and insulators!

However, they are very complex, this can be demonstrated with math or Roy's excellent little visual aid, EZNEC.

I don't think you are a "smart ass" or "diabolically argumentative", you are simply lost in this--as we ALL are.

It is a learning curve, some here help speed us along this curve, some offer "other things." I know what you mean.

All antennas end up being a compromise of size, building ease, materials, weight, wind resistance (wind loading), what neighbors will tolerate in "artistic design", directional patterns, cost, etc., etc.

Really, there is no such thing as "the most efficient" antenna--least not when you have to design an antenna for the real world. I think most answers to your question(s) will seem vague to you, this is not because of deliberate intent on those answering, it just goes to point out the complexity of your most "simple questions" and the different interpretations which can spring forth from even the most simple question.

Patience is a skill which benefits one in all pursuits one engages in...

Warmest regards,
JS

If a simple dipole is fed with 100 watts and radiates 95 watts, it is 95% efficient.

If a simple Yagi is fed with 100 watts and radiates 95 watts, it is 95% efficient.

If a full size 11 element Yagi is fed with 100 watts and radiates 95 watts, it
is 95% efficient.

What is your real question regarding efficiency?

How are you measuring the antennas "output" or "radiated power?"
--and--
How much of that 95 watts is spent in heating the dielectrics and metal
(or is that "missing" 5 watts the heating power? And, how did you
measure that?)

Pretty much any ole wire you attach to it will work. Like one said,
local
noise can be an issue in some places, and that might cause you to
vary the design a bit. If any of those old radios use the loops for MW,
I
would keep those intact. The loops are usually by far the best for the
MW
band. Only use the wires for SW.

It troubles me that so many wish to "hold court" on this NG. Establish
obscure, bizarre or downright wrong rules of discovery to pump up their
own egos. So much opportunity to share advice in a collegial fashion,
realizing the breadth (or shallowness) of understanding that exists
amongst "us".

Is Elmer really dead?

> resistive value of the impedance which means losses ...

Actually Art, adding reactance reduces the current in
the element thus *decreasing* losses below what a resonant
passive element would have. Pure reactance is lossless.

Seems to me that the reactance in the passive elements
provides a phase shift that causes destructive interference
in the desired places and constructive interference in
the desired places.

I came in late and thus apologize if anyone else has stated
this earlier.

Hi Alex, You sound like a brand new no-code Tech. Welcome to ham radio.

All those computers you mentioned will work fine, but if you really want to do any serious computer work you're going to want to invest in a Vic 20, or a TI-99, or a Commodore 64. Power users swear by'em.

Dear MP,

Please pull your friggen head out of your ass and use your brain for once.

Smoke signals are a line of sight form of communication and you can't see
them at night unless the fire is extremely large, and smoke signals don't
work well in natural disasters like huricanes and tornados. Blind people
can't see them either, they can only smell the smoke.

CW works well all the time, unless you're too lazy or dumb to learn it.
In which case you'll probably want to stick to playing with your matches
and smoke bombs.

Yes unfortunately and an awful lot of them too.

They all hate the CW requirement and want ham radio to get dumbed down
more, but if I had to single just one of them out for a good slapping, I'd
probably say it's Markie that needs it the most.

Now if Markie learned cw to 13 or 20 wpm, I'd congratulate him
and say, "Welcome to Ham radio Markie."

I know what you mean Dan. With the anticipation that ham radio is going
to get dumbed down again real soon, the dumb-it-downers like Lenny,
Markie, Opus and a few others are really trashing the groups with anti
code test hate. We can only hope the code requirement is retained and
increased so that they can't get on HF and mess that up too.

3237. Re: Yagi efficiency

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-03 00:35:57 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1165106157.577563.301620@l12g2000cwl.googlegroups.com>
Source record: 48711

My thoughts exactly information is not really sort only an excuse to
snipe
Movement in any science is by increments of knoweledge though I do
believe absolute miricles do occur Seems like people only want
questions that they have answers for not items that create original
thought. Seems also that many believe that radiating methods have been
exhausted but every year the patent ofrfice issue different designs. I
have found during my life when I have been given a patent that people
will say thats obvious or I knew that or that should be shared with me
evry one being after the fact. Such people are not interested in
anything new unles they read about it in a book or they will state that
they do not understand. I started out with the intent of explaining a
new technology with respect to radiation but I cannot continue as we
have sniping starting with the question. A few months ago I started
with a question and nobody liked it so after some time I decided to
word the question as they said it should have been stated......Well
they have now donned different hats and are aiming for the original
question again.. You just can't win if you are in a information sharing
mode with people who are confinced they know it all and that is why
they are sniping. Now since my education value is considered in doubt I
will back off so that those who perceive themselves as experts will
carry on the load for others who may be interested in knoweledge but
only if they know everything such that they can critisize.
Has anybody pointed to a flaw in the Yagi design and the cause of it
and what idealy could be done to improve things? Ofcourse not, their
forte is to throw stones pure and simple.
I can understand it from Roy since he has a personal financial interest
in conversations revolving around Yagi antennas. But some of the others
have been known to produce absolutely nothing to the subject. Even
Cecil who I suggest with his extra deep physics
education gets mocked sometimes from people with I suspect just a high
school graduation that is the school stood on a hill. Check out the
responses so far to get an understanding
of the people that you are dealing with starting with Turner who with
his vast background of educatiate has taken on the task of judging mine
as demeaning as one of the lowest of the low. What has he achieved in
life or with antenna design to allow him to assume the mantle of
nobility which he does not share so that others may learn? Are there no
positive thoughts out there about antennas or to phrase an answer to
what they believe is the question. ?
At the moment I have only heard about negatives that prevent posting
from showing their expertise that they believe they have and where at
the present time we can only trust.
Has anybody supplied a efficiency number of anything to do with this

question or what they perceived was the querstion explaining in detail
how they arrived at a particular position rather than just guessing,any
one, anybody nothing positive anything positive?

Cecil:

On the surface, this is all very correct, however, you cannot induce reactance without inducing some value (albeit it may, or may not, be trivial) of pure resistance (ohmic dc), barring the use of superconducting material, of course.

I think Art does see that that either magnetically or capacitively (and both most likely) the resistance and all other aspects of the director and reflector are being introduced into the driven element's circuit. This I see stated in his original post and ...

However, how big is that fly speck(s) under your microscope is yet another question and those answers ...

Warmest regards,
JS

David if you had a dipole that had inherrent directional capabilities
would you consider
that as a possible choice for better efficiency ? Where does the 95%
number come from and where did the 5% go so. Did turners post influence
your guess at that number? is he worth copying? Others can get an idea
what you are talking about ie. parameters of use for which you are
applying the 95% figure to. It is possible that we can at least one
negative from the discusion in search of the kernel of info. Does the
dipole become more or less efficient as it moves away from its design
frequency as it becomes "detuned" Give me some meat

No Jerry you are on the right path, the envelope under question is the
application of power that produces the emmission of flux in the near
field You have to be carefull as to what radiation refers to and where
or sniping will start because some radiation starts in the near field
does not really take off because of radiation that cancells or
neutralises the emitted flux
so far field radiation does not occur so you have to be carefull after
the flux flows when you really only have two fields acting in concert
You will also here people refer to the gain of a radiated field as an
indication of efficiency which is just comparing the position of choice
to another position iof choice without regard to the volume enclosed in
a radiation field which is normally spread in all directions whether
you want it or not. So we are looking strictlyat how much energy we
lose in the providing flux emmisions which profides radiation without
concern where it goes otherwise you will get into a sqogmire of
confusion. Frankly I can tell you that a element detuned is the root of
all the inefficiences experienced with a Yagi.Period
but others resist this notion or fact
Art

ABSOLUTELY NOT!!!!

Efficiency is the ratio of [power input minus power losses] divided by [power input]. PERIOD!!!!!!!!!

If it's anything else you have created a perpetual motion machine ... patent it!!!

This thread has been corrupted by confusion with directivity and gain. Neither of which have anything to do with efficiency. Antenna patterns provide zero information regarding efficiency.

It is possible, for this discussion, to have a Yagi with 10 dB gain, -60 dB backlobes, and 10 dB losses and it is only a 10% efficient antenna that exhibits a gain of 0 dBd. It is still 10% efficient.

Art, who made the original post, has to resolve his difficulties with antenna efficiency, antenna system efficiency, path loss effects, gain and directivity.

Cecil, as an engineer, you should not slide into loose definitions of efficiency. Doing so only further confuses the issue.

Art is using 'efficiency' incorrectly. His actual interest is in the total path loss from transmitter to receiver and should be dealt with in that context. And in that problem, path loss, the issues are further complicated between line of sight, ground wave and over the horizon propagation effects. HF path losses can have -60 dB variations, or more loss, depending on propagation, solar cycles, and solar storms. We have all experienced QSB of up to 5 S units and also total loss of signals due to solar effects. These effects are NOT YAGI ANTENNA EFFICIENCY.

Hi Art

Does that mean the Yagi gets hot when used to radiate RF? That is,
since the Yagi is less efficient than some other reference antenna, the Yagi
gets hotter than the other antenna when their input power is equal.

I understand where you are coming from Cecil but let me turn your
statement around. How are you going to account for these additions and
subtractions in accepted equations by the masters that produce the
legitamacy of RLC or complex circuitry equeationd if they are known as
loss less and not a lumped item around which electromechanics thrive?
Cecil Moore wrote:

value
as cos phi or power factor but it is a variable and not a constant
which circuitry requires.
Remember only R is of consideration for the addition of power from each
element which provides flux unless you can quantasize reaction for me
as producing the emmision of flux other than a indication of the
direction it takes . Really Cecil I am trying to get people to think
about elements containing inherranr directional properties so that
uneeded radiation is harnessesd for useful purposes but they are
shutting their ears.

Yes Jerry, if the radiation efficiency falls, the antenna should get
"hotter", where else would the lost power go? Harmonics? Psychic waves?

Help me help me please , a detuned element has a reactive impedance value, simple fact.
Now with your superior knowledge and education show not just me but all of us how the production of a reactive impedance does not or cannot impede the formation of emmited flux? I dont want just comments or guesses just an explanation of your position which aligns with the laws of Kirchoff, Ampere, Green ,Laplace etc as a group or as single people to give your response some credability . Cecil has given you a starting point as to what exactly reactance is so the rest should be easy for you considering how easily you can dismiss my logic and education regarding the Yagi antenna. Bill I cant wait to hear the mutterings of a master of your station, a chance to learn something really new, maybe not even written in a book Go man go! Well I know you can't.... but I am just demonstrating that if you want to snipe then others will be encouraged to snipe and it is not nice. Knoweledge is what I am after not errent gun shots

>From a theoretical way of getting at the answer it seems
a logical way of proceding. So now to the rest of the task.1 how do we
determine volumes that you talk about that are a result of deflection 2
How do we determine
radiation that was cancelled or neutralised and 3 How do you determine
the radiation volume created by ground reflection so we can work back
to search for ground losses. That last one really bothers me as I have
never got a good handle on the contribution of ground reflection to any
particular part of the radiation envelope.

SNIPPED

Art, It has absolutely NOTHING to do with measurements, or with 95 watts or 5 watts, or antenna patterns, or the reactive components.

It is defining efficiency properly!

Net radiated power divided by power input is Efficiency. Measure it or calculate it any way you want!

An antenna with -3 dB loss is a 50% efficient antenna independent of the actual input power. Choose any power input you like. An antenna with -3 dB loss is a 50% efficient antenna regardless of gain, directivity, antenna patterns, patents, claims, marketing Bull S--t, or anything else.

Put your favorite antenna inside a sphere of any suitable diameter that contains the antenna. The total rf power coming out of the sphere divided by the total rf power into the antenna [sphere] is the antenna efficiency. There is NO OTHER definition!

Reducing power in the back and side lobes has absolutely NOTHING to do with efficiency. It has to do with directivity.

Design of a Yagi, traps, conductors, element spacing etc. will produce variations in gain, directivity, efficiency [variations in losses, heat]. Practically, the difference in efficiency between a 90% efficient antenna and a 98% efficient antenna is swamped by variations in the path loss physics.

I spent years of my life designing rf systems for telemetry from space vehicles through reentry to a ground station. Data integrity at the ground station was and still is the dominating requirement. Based on allowable data error rates, the total path equation required S/N ratios of 12 dB or more. The solution is a systems solution where the minor variations in antenna efficiency get lost in the calculations.

NOT CORRECT! It is a complex impedance that contains both a resistive and an reactive component.

Well now I am not sure what you want plotting if you are making the
reflector resonant
other than the design frequency of the array.

Art:

No, the reflector would remain the same ~5% longer (electrically and physically) than the de. And, the director remains physically shorter than the de, but made resonate with the proper addition of a coil, somewhere in its length, so as to be made resonate at the same freqs as the de (or approx. so, since the coil will undoubtedly change some characteristics from that of the resonate de.

Art, you are rapid losing me here. Either I am not able to see what you are getting at, or else I suspect you of having some facts or formulas twisted about here...

David are you going nuts? I used the word impedance whichcan mean two components only one of which is used for power. What on earth are you trying to say now or are you looking for a reason to thro stones. Now calm down and point out where I was not CORRECT as you put it and what are the consequences of this error relative to what we are talking about?
If your point is that I didn't emphasise the word complex then there is no need to respond, you can have it your way I don't mind if it helps you out with your apparent anger.

Tom it is no good plonking me for what david is saying because he is
not quoting me, in fact some of it is a requote of what he said not me.
I think he is creating a straw man that he can argue with, is that what
you call reality? He has spent most of his time in space and I believe
him

Hi Art

If this was a car news group I'd realize that you have left me in your
dust. I just cant keep up with you. I thought I understood antennas and
I even thought I could design them. But, I dont even know the meaning of
the words you use, and I am too lazy to study and learn about things like
"emission of flux".
I had designed and built some Yagi arrays that worked pretty but I was
never aware that I detuned any of their elements. I just thought they were
as efficient as any other array of similar size.
It is obvious to me that I'll never understand why those Yogis are
considered inefficient.

Jerry

Well I obviously misunderstood the question
What I have done is to make elements resonant with possesion of
different lengths
This is not that unusual with antennas. Now 'how' you make a shorter
element resonant at the same frequency is where we part. I would make
the element resonant by the addition of nearby elements not by adding a
constant like an inductance ,so obviously I have not plotted anything
according to what you are pointing to

It got "dumbed-down" when a license was issued to you.

BTW, what is your call?

I wouldn't worry about that, you have made them and they work in a
manner that satisfies you what more could you want of an antenna?
Remember an extra DB in performance lookes like an achievement when
dealing with design but the fact is you would not see a difference if
you upgraded your antenna, so efficiency is not a factor for you as a
user. Increasing efficiency is just one small step that when added to
other small steps it gets everybodies attention it is at that point you
will take the step to upgrade. Enjoy and remember efficiency is a very
relevant term as it could be refering to something that is desired but
impossible to improve

Art:

First, you must learn "theory" (and there IS a reason they term that THEORY! it is JUST THAT!) the way they learned it, so you can quote it to them verbatim, else they can't relate, else they are quick to dismiss. It helps if every once in awhile you say, "I know the accepted way of thinking says this, or that... but what about this other, or that other?" (yanno what I mean?)

Then you can really begin "thinking."

However, that is not all bad, it gives common ground so we ALL can communicate on a level which gives some understanding and purpose, perhaps to a final goal ...

... and beware, there are "other thinkers" here, they just choose to remain hidden and duck the wrath and arrows of the "rote-ly educated."

3275. Dipole with inherent directional capabilities?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-03 03:59:35 UTC
From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1165118375.085196.69960@j72g2000cwa.googlegroups.com>
Source record: 48649

Art,

I want to know about this concept. Can you tell me how to build one?
By what means might it change the very simple calculation of efficiency
given in the long and rambling thread which I am trying to avoid.

Take an antenna, any antenna you can dream up, measure the power
radiated in each direction. Add it all up. Compare that to the power
fed to the antenna.

A 100% efficient antenna radiates all the power it's fed.

A 50% efficent antenna radiates half the power it's fed.

A 150% efficent antenna radiates half again as much power as it's fed.

Why is an inherently directional "dipole" different from a yagi in this
respect?

Dan

Source record: 48651

Well I obviously misunderstood the question
What I have done is to make elements resonant with possesion of
different lengths
This is not that unusual with antennas. Now 'how' you make a shorter
element resonant at the same frequency is where we part. I would make
the element resonant by the addition of nearby elements not by adding a
constant like an inductance ,so obviously I have not plotted anything
according to what you are pointing to

If you want to go slightly higher tech you could use a Heliograph. Of course they don't work at night either or on a cloudy day but the signal can be directed like a beam antenna.

Dan:

I am not Art. However, the questions look so ridiculous, let me provide some possible answers.

> A 100% efficient antenna radiates all the power it's fed.
ANSWER: Impossible. Well, outside of a superconducting physics lab anyway !

> A 150% efficent antenna radiates half again as much power as it's fed.
ANSWER: Again, impossible at this time, maybe in the future? Perhaps aliens know how to do that?

> Why is an inherently directional "dipole" different from a yagi in this respect?
ANSWER: A dipole has "inherently directional properties", perhaps given it by its creator? God? The laws of physics? Aliens? Well, it just has them! And, you ask, why are they different than a yagi's? Geezh, does a darn dipole even look like a darn yagi? I mean, come on, give me some room here! Ok, let me give you a clue, there is more metal and dielectric material in the yagi, that is why! <grin>

I think the top, very top efficiency of a silver plated-glass insulated antenna in earths atmosphere, and with ample surface area to less "skin effect" (probably space too, but there is moisture/oxygen/nitrogen/carbon dioxide/etc. factor to atmosphere) is ~98%. When we finally understand the ether's relationship to an antenna, it would NOT surprise me if we can bring that close to 99.99999999999999, not a great improvement--but hey, it gives me something to think about.

Oh yeah. That ~98% figure, that took for granted the antenna conductors were chilled at or very near superconducting temps. or, the conductors were constructed of a "yet to be developed" superconducting material. But, certainly, you picked up that, that was implied from my previous text.

In fact, the skin effect is a phenomenon which could consume a whole book to itself. I mean, why rf chooses to only travel the surface of metal conductors? (why would the surface of metal offer less resistance than the atoms of the metal inner most? Indeed, if you make the inner material of silver and the other covering of a conductor of iron, it still attempts to favor the iron!) Almost leading one to believe it (rf) is attempting to "leap to the superconducting ether", but then, I dream a lot ...

The radiation IS NOT cancelled or Neutralized. You need to learn more about what is going on with an antenna. I suggest you do some serious reading, actually reading with an open mind and not reading trying to find little phrases that seem to you to prove your beliefs. It should be fairly obvious that if an antenna worked by neutralization or cancelation that it would take more energy to cancel out radiation in the undesired direction of a yagi than is available in the desired direction. Therefore a Yagi or any other antenna does not work by cancellation.

I gues I could express this a lot better but its late and whats the use.

John,

Obviously you can have neither a 100% efficent antenna nor a 150%
efficient antenna. That doesn't change the definition of efficiency.
That was my point. It doesn't matter if you're talking about possible
or impossible antennas, efficiency is power out divided by power in.

Also, yes, a dipole has directional characteristics, but it would seem
that Art is talking about something more directional than a dipole that
is not a multielement array, and he asks us to imagine a dipole with
inherent directional capabilities

This suggests that it doesn't have the familar dipole directionality,
but something else.

What is that something else? How does it bear upon efficiency?

Dan

At resonance it is the antenna as a whole that is resistive not just the
driven element.

> components only one of which is used for power.

No! You used the phrase "reactive impedance".

That is significantly different from "Complex Impedance"!

XL [2*Pi*f*L] is a reactive impedance, not a complex impedance!

XC [1/(2*Pi*f*C)] is a reactive impedance, not a complex impedance.

R[Rr + Rloss] + j[XL] is a complex impedance.

I still say you're using technical definitions that do not conform to the
standard definitions.

Art,

The dipole elements (of all lengths) in a Yagi _do_ have their own directional properties, and generate their own radiation patterns -- the fields of which add/subtract in space as a function of their relative magnitudes and phases to produce a net field that varies around the radiation sphere centered on the antenna.

From reading between the lines, maybe you are relating antenna efficiency to the free-space field strength that the antenna produces at a given distance and direction in the far field when a given amount of r-f power is applied to its input terminals, compared to the field produced for the same conditions by a reference radiator such as a 1/2-wave dipole, or an isotropic source.

For this definition it is reasonable to expect that both the test and the reference antenna have negligible conductor and dielectric loss, and that they both present a return loss of 30 dB or better to the transmission line leading to the transmitter. All of that is practical to achieve. Also note under these conditions that a return loss of 30 dB means that 99.9% of the power applied to the antenna is radiated (somewhere), so if that is the meaning of antenna efficiency, it is high indeed.

By this definition, the efficiency of a Yagi in its direction of maximum field is very high, and does not indicate that sub-optimal choices were made for its mechnical layout. In fact, the inventors of this antenna and many others have spent much time and effort with physical and electrical models of the Yagi to optimize its patterns and gains. The result of all that finds that the director(s) should be shorter than the driven element, that the reflector should be longer, and that using more than one reflector has minimal effect. That is the "bottom line," and speculation to the contrary won't change it.

Using this Yagi design and this definition of efficiency, a standard, 6-element Yagi has a main lobe peak efficiency of about 250% compared to a 1/2-wave dipole, and 316% compared to an isotropic radiator, which correspond to radiated power ratios of about 610% and 1,000%, respectively.

IEEE Standard 145-1983 gives the standard definitions of terms for antennas (gain, directivity, efficiency etc).

>> shutting their ears.

every thing that radiates has 'inherent directional properties'. it is
those properties that software like nec models. adding up all the
contributions of lots of little tiny pieces of radiating current is what
goes into designing all sorts of antennas, including yagis. there is no
magic wire that is going to get more power on target, no strange property
that is going to give you super gain, and no way to get rid of all the
'uneeded radiation'. There will always be some losses, power going where
you don't want it to, etc... believe me, many phd's have made their life
studies of reducing that last little bit of radiation off the side or back,
and the conclusion is??? you can't do it. there are many volumes on how to
reduce it in different cases, lots of spectacular designs that are totally
impractical for ham use, and some super applications of standard techniques
for things like the deep space network and radio astronomy.. but there is no
magic in a wire, no matter how you bend it or where you stick it.

Well, the unit arrived Saturday and I tried it out. This must be a city version where people are crowded together. It's range is 30-75'. I need it about 30' away from where I'll receive the final signal. Generally, I can hear it, but have to do some fussing with the FM rcvr. Well, I'm not done with the testing yet. They suggest putting it up high and/or putting a piece of metal sheet under the xmitter. I had hoped for a xmission range of 100' or more to get the signal to an out building. Maybe they have a 'country' version. Yikes.

As soon as you explain what you mean by "efficiency" I can answer that in detail..

What do you mean by efficiency? Is efficiency 100% of applied power being in the forward lobe and 0% in sidelobes or rear lobes? If so, better get a new hobby because it ain't gonna happen... Can't happen due to the laws of physics... For discussion I'm going to assume that this is your goal... Let's go up a bit in frequency where the antennas are small and easy to work with... Telescopes... The only difference between blue light and 20 meters is the frequency...

Now those telescopes are some really high gain antennas.. So, here we have this super, duper, high gain antenna (I don't know what the gain in DBI is, but it is huge, man, huge)... And we point it at a really faint signal, say the star Rigel - which is an Isotropic radiator - a point source... And we adjust the resonance (focus) for the best possible signal we can get... We put a slit on the telescope and scan across that signal and <gasp> it has side lobes! Not all the power <luminence> is in the main lobe... Mathematically there will always be side lobes off the main lobe... By reciprocity, it is impossible to focus a point souce of light down to a point... The center brilliance will be sorrounded by circles of confusion <lobes>... Like wise it is impossible to build an antenna that has a response that is only a single main lobe and no side lobes...

'Now, we can build arrays of antennas that enhance the main lobe and diminish the side and rear lobes through pattern multiplication, and we can get those unwanted lobes down to a few thousandths of the power in the main lobe... One way is a broadside array of six of a dozen, or so, more point sources with half wave spacing and fed in Quadrature, or other current variations... Krause's book has a good set of patterns and explanation of this method of synthesizing an antenna that is very "efficient"... <efficiency being defined as I 'assumed' above>... However, these antennas are not efficient in terms of time, labor, size, cost, and complexity...

So, to reiterate, go to Reisert, and Krause, and Terman, et. al. to find your magically 'efficient' antenna...

denny / k8do

btw, a thought just caught me... W8JI on his web site has a great table of antenna 'efficiency' in low noise receiving antennas... Maybe this is what you mean... GO look it up..

3298. Zero Sidelobe Antenna Design

> is??? you can't do it.

Just to note that an inline array of radiators spaced 1/2 wavelength apart and fed with equal phase, but binomial power distribution produces a radiation pattern with zero sidelobes, and an infinite front-back ratio. These designs are shown in chapter 5 of Kraus' "Antennas for All Applications," 3rd edition.

Such antenna arrays have been marketed by FM broadcast antenna OEMs to reduce the power density (radhaz levels) on the ground around towers with high power FM systems on them.

Read the chaper again... That is an inline array of point sources... A different kettle of fish from an inline array of real, physical antennas... Now, you may approximate this stellar performance by going to very short radiators with capacity hats on the ends, etc. so that the current distribution across the radiator approximates linear, but the price you pay in matching the source and feed line to these near point radiators ought to keep you busy until you meet the requirements for social security... These are not what I would consider efficient antenna arrays...

> Such antenna arrays have been marketed by FM broadcast antenna OEMs to

Gosh, I don't see CushCraft offering any such arrays for 80 meters - I sure could use one!!!

The example in Kraus showed isotropic radiators, but the same zero sidelobe, infinite F/B descriptors for the array pattern apply for any pattern shape generated by the individual radiators, as long as they are the same.

The FM broadcast antennas I referred to use standard FM c-pol elements fed as I described, and have these characteristics -- except for re-radiation by the tower.

Set up a simple NEC model using dipoles, and check for yourself.

Or you can look at mine in paper 10 at http://rfry.org

Hi Denny

You seemed to have missed the point completely. Maybe your news reader didnt supply you with the original post where Art refers to Efficiency of a Yagi as being low.
Art finally agreed that the efficiency he refers to with his Yagi is the Power IN divided by Power Out kind of efficiency. Since I consider the statement that the Yagi antenna is I squared R lossy to be entirely erroneous, I realized that I had no place in such a frivilous discussion. Now I find it difficult to understand why you want to write so extensively about telescopes, and broadside arrays, and sidelobes when we are considering Efficiency. You may want to refer to Apperature Efficiency, but, you are doing a poor job of it.

Whats with you Denny??? Why do you think of yourself as so superior that you raise your voice at me telling me to "GO look it up".

Jerry

I assume you are saying that lengthening a passive
element increases the ohmic losses? Then wouldn't
shortening a passive element, to induce capacitive
reactance, decrease the ohmic losses? And in either
case, since reactance reduces the induced current
and since ohmic losses are proportional to the square
of the current while only being proportional to the
first power of resistance, wouldn't that still
decrease ohmic losses?

Can people who live by the trivial sword, also
trip and fall on that same trivial sword? :-)

>> Not if the question is: What is beam efficiency? :-)
>
> ABSOLUTELY NOT!!!!

From "Antennas For All Applications", 3rd edition by
John D. Kraus and Ronald J. Marhefka, page 665:

"Turning now to the *beam efficiency E(m)*, or the
ratio of the solid angle of the main beam Omega(m)
to the total beam solid angle Omega(a), we have ..."

All emphasis is the book author's, not w5dxp's.

From "Antenna Theory, Analysis and Design", 2nd edition,
by Constantin A. Balanis, page 63:

begin quote:
2.10 BEAM EFFICIENCY

Another parameter that is frequently used to judge the
quality of transmitting and receiving antennas is the
beam efficiency. For an antenna with its major lobe
directed along the z-axis (Theta = 0), as shown in
Figure 2.4(a), the beam efficiency (BE) is defined by

power transmitted(received) within cone angle Theta(1)
BE = --
power transmitted(received) by the antenna

end quote:

In trying to figure out what definition Art is using,
this definition seems to me to be the closest.

3306. two stacked yagis vs one long yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-03 15:54:37 UTC
From: N4aeq <tucker@conninc.com>
Message-ID: <1165161277.556098.152350@79g2000cws.googlegroups.com>
Source record: 48580

First off if size is no problem then what would be the advantage to two stacked yagis opposed to one long yagi, considering the gain of each setup would be equal?

3307. Re: two stacked yagis vs one long yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-03 16:02:50 UTC
From: Dave <noone@nowhere.com>
Message-ID: <y5-dnaUybeCxaO_YnZ2dnUVZ_omdnZ2d@crocker.com>
Source record: 48581

the gain probably wouldn't be the same... but the advantage of stacked yagis
is that you can fill in the gaps in the vertical takeoff angles that a
single yagi has with the 2nd, (or 3rd, or 4th) in the stack.

> direction it takes .

I assume you are talking about radiation resistance.
There are other R's that cause loss of desired radiation
including conduction-dielectric losses. Some signal
is lost to the ground after being radiated.

Assuming that your definition of efficiency includes
beam efficiency, I would suggest taking an optimized
two-element Yagi into EZNEC and determining the maximum
gain. Then replace the reflector by an element identical
to the driven element including the source signal. Using
the same amount of total driving power, if you can come
up with a gain superior to the Yagi, would that prove
the point you are trying to make?

It was more than likely an inclusive statement, not an
exclusive one. I suspect Art meant, "a reactive impedance
term value" when he said "a reactive impedance value".

In a lot of areas - the FIRE DEPTS. don't approve of OPEN BURNINGS - so
I guess that means that you would have to get the local fire depts. blessing
prior to your disaster to use smoke!

Reference to the subject - if one did not want to use pure CW (if there
is a mental or physical block from learning it) - there are other digital
signals that could be used, i.e.:PSK31, etc.

Other line of site communications could be - focused white light beams,
Lasers, flags, etc.

I think the real issue is that you and some of your friends are just
plain against CW, (and you want to turn everybody else in that same
direction), you don't use it, you don't want to learn it, etc. If that is
the case, then why don't you just drop it - QUIT NAGGING LIKE AN OLD LADY -
and go onto some other subject or project?

The CCrane version is a "full gallon" as far as the FCC is concerned.
I have one which covers my house, and 3 acre yard, with full quieting.
It is on the ground floor of a frame house, and sits on top of a metal
filing cabinet, and works equally well on top of the tuner/amp. I
have found that, as you would expect, the signal improves modestly as
you move to higher TX frequencies.

Infinite F/B ratio? I get the impression that we're talking about a multi-bay FM antenna that should be omnidirectional in azimuth... Do you mean infinite horizontal to zenith ratio? Or Front-to-Side ratio if it were installed horizontally? Maybe I'm missing something. I guess I'm missing Kraus's book! We're not talking a unidirectional beam here, right?

A 5x5 planar dipole array with a 2:1:1:0.1:0.1 ratio spaced on a 1/2 wavelength grid gives a nice clean bidirectional beam with "no" sidelobes.

A pair of these arrays spaced 90 degrees and fed 90 degrees makes a nice unidirectional clean beam with good F/B and low rear lobes, and no front sidelobes.

Not envious of someone who tries to build a distribution harness for this thing, though.

The radiation is not cancelled in the way ART means, One of the problems of replying to his post is you can not do really do it without sounding like an idiot.

>
> Doesn't the performance of non-reflecting glass
> depend upon EM wave cancellation?
This I can respond to (though I doubt that I should)

The term usually used is "anti-reflective" and refers to a specific
multi-coating technique on the glass (or other medium).

the "anti" refers to destructive wave interference for reflected light
by varying the refractive index of successive coatings. Thus, MORE of
the incident travels through the medium than is reflected back

If the goal is to increase the % of light refracted THROUGH the medium,
then anti-reflective coating increases the efficiency.

Take the same glass without the AR coating, and LESS light is refracting
THROUGH the medium (more reflecting back): lower efficiency.

This definition of efficiency only makes sense when you're interested in
light refracted through the glass.

P-in / P-out does not = this definition of efficiency.

The efficiency definition implies interest in directionality.

Is this not where the confusion lies in all these posts?

John

PS,
Think of a simple flashlight with a mirror and a lens.

As a simple analogy, the filament of the light is the driven element
with a mirror behind and a lens in front...a LIGHT Yagi, no?

No diff in P-in/p-out...just all light directed out of the flashlight
into a beam.

This current that you are referring to, I used P =I squared R
which leads to lower power. Where did I go wrong

Yes, forgot about the SDK-85. Used that in tech school way back in
1981. That was a smoking little bare-bones computer system...

John,

You're right about the efficiency, but be careful with the flashlight analogy. A light yagi might have ~ 200 nanometer long elements.

An 20m band reflector analogous to that in a mini maglight would have to be 800 miles in diameter.

The analogy with respect to efficiency is fine... but there's no HF antenna that can form a beam like that.

73,
Dan

Interesting Jimmy
Could you show me how me how a vector directed at a socalled reflector
behaves with respect to a constant plane without the implication of a
neutralising effect.
Now the reflector "works" only as a part of a particular plane so
please go on from there.
I often read of additive and subtractive radiation in books written by
the masters and I have seemed to have got the wrong idea about these
matters
Art

I agree there are other losses but to prevent including losses that are
outside the E and H process change over such as ground reflections etc
is it not better to just accept The pure resistance only so there is no
need to characterize individual losses Once you go beyond the near
field it gets complicated as losses are created outside the EH
generation process.
Ii am not sure how the EZNEC thing functions but if you design the
array where all elements are driven you can then use the individual
element impedances to determine overall efficiency.i.e. power in versus
power out
Fortunately thats the way my program can operate

> trip and fall on that same trivial sword? :-)

Cecil:

Yes they can. And, that would be no trivial trip! It is just, in the dark, like I am most of the time, I can't seem to avoid them, the trips.

However, what I am saying can be proved, or disproved in the real world. What I am saying, is construct a SHF antenna and chuck a xmitter and pa behind it. Encase the antenna in good insulating (polyurethane foam for instance?) material and have a temperature sensor attached to each element. Crank up the power and you will see some sort of rise in temp in the director (indeed, it should be seen in ALL elements), since heat = loss (actually, since we all accept the law of conservation of energy, loss is a misnomer, really it is only a change in frequency, from rf to infrared--beware a trivial trip!) we demonstrate an induced loss in the system.

Next, remove all elements and materials to a distance from the de where absolutely no coupling can occur. Tune and match the de to the pa output, now bring the director into proximity to the de, observe the power flow to the de as you finally set the director into proper position to form a good frontal lobe, you MUST now re-tune and adjust the de, this is because electrical factors (resistance, reactance and possible other factors we are not even aware of) of the director are now being "mirrored" into the de (an ohmic loss (heat) should also have risen in the de due to the mirrored directors imperfections.)

That is all I am saying. Now we would have go get out our equipment which can measure the weight of fly wings to know the real importance of all that...

Geesh Cecil, you never ask ANY simple questions!

Warmest regards,
JS

> The radiation is not cancelled in the way ART means.

Sorry, I came in late. Here's a quotation from a web
site concerning wave cancellation that might help:

"... when two waves of equal amplitude and wavelength
that are 180-degrees ... out of phase with each other
meet, they are not actually annihilated, ... All of the
photon energy present in these waves must somehow be
recovered or redistributed in a new direction, according
to the law of energy conservation ... Instead, upon
meeting, the photons are redistributed to regions that
permit constructive interference, so the effect should
be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction
or destruction of light."

If the EM energy doesn't change form, the destructive
interference from wave cancellation must result in
an equal magnitude of constructive interference
somewhere else - like squeezing a balloon. Sorry if
this has been said previously.

Lower power results in lowering the loss due to heat.
That leaves more power available to be radiated by
the antenna system but not necessarily radiated by
this single element that we are discussing. I suspect
two driven elements are theoretically capable of
better performance than a two element Yagi given
equal total power input into the elements.

> test
> of the RoomCap with this antenna.

Now, an additional comparison was made,
now between RoomCap and Magloop antenna.

Since long time it was my desire to compare the RoomCap antenna with a
good
magnetic Loop antenna.
On November 30th 2006 this test took place.
The test was assisted by Edy, HB9EBG.

Comparing antenna = Magnetic Loop, 85cm diameter, 35 mm diameter of
tube, copper tube, silvered, with Annecke butterfly capacitor with
remote tuning, in vertical position.

Test antenna = RoomCap for 20m, 5cm diameter, length of radiator =
150cm, without top capacity.

Both antennas were placed at the same height (150 cm above ground) in a
free field,
using the same 100 W transceiver, and adjusted to VSWR 1:1.

In total, 13 comparing QSOs were conducted in the time between 13.30h
to 16.00h.
In each QSO the antenna was quickly changed many times and the remote
station
was asked to indicate the average signal strength difference between
the two antennas.

In all contacts the RoomCap was reported clearly as the stronger
antenna, where the
smallest reported difference was 1 S point and the largest difference
was 5 S points.

Here follows the list of the reporting stations with the indicated
difference in S points.

YO5PDW + 1
LY3ZM + 3
RU6AH + 1
UA3AIU + 1,5
YO3AJN + 2
EA8BRW + 2
LY2SP + 4
UR0EA + 2
YO4AAC + 1
UT8NF + 1
YO6KSU + 2
UR5HDE + 5
SV0XBA + 2

This corresponds to an average difference of 2.11 S points.
An S point is defined as 6 db, resulting in about 12 db advantage.
(It is clear, that the receivers many times do not follow exactly
this definition, but in the average this may be close enough.)
In other words:
The RoomCap radiates about 15 times stronger than the Magloop.
(15 times the power).

Thanks for the response, Dan.

I'm not sure a yagi in it's HF form can work at all in the visible spectrum. I just wanted to treat the yagi notion of a reflector and director as it occurs within the light spectrum (form isn't important): directional efficiency is what I was trying to get at, and seems to be missed by some posters

It has been my experience that a single, long Yagi has a narrower beam
width and a narrower bandwidth.

A longer one is easier to feed than a stack but harder to keep in the
air... If the birds like sitting on one end...

One advantage is that you can dual-feed them all the way from the shack
and, with proper phasing control, can actually manipulate the take-off
angle. Plus they tend to be less sharp in the azimuth plane (not so
pointy).

Exactly.That is similar to two equal forces acting to compressa piece
of steel Opposite to when you use tension the side forces press inwards
until a 45 degree break or shear angle occurs where the vectors forces
move out at right angles to the compressive force Newton is correct,
you cant destroy energy

More current is not necessarily used for reradiation .
You also have circulating current because of inherrant
inductance and capacitance since we are dealing with a series
circuit. You can add resistance to the circuit when you are at
some distance from resonance which is similar to forming band
pass shapes but the bottom line is that at resonance or near
resonance pure resistance rules To get closer to what is really
happening is to go back to 455 khz when used in radio
circuits to revive the memory

When I don't agree with them they call me names It is always them or
their followers and I eventually retaliate with a vengance and I think
I can do it better than them.
They are of a group that everything is known about antennas and is
written in books. If you refer to something that is not in the books
then they attack where I wish they would take a bit of time trying to
understand what I am getting at so I can make use of their superior
knowledge outside of yagis but yagis dominate their whole life to the
exclusion of anything else so we are at an impasse. Tough but it is of
their choice where I have offered my hand many times only to be
rejected.

Part of my problem is that the radio in the bedroom, where I do most of my listening, is right near the noise source. I need the source on all night (CPAP unit). The best reception of my favorite station is 30' away, across the house, and I may not be able to find a better spot for the xmitter. Oh, well, I'll keep playing with this. Higher tonight. (My rcvr is it a Crane's getting repaired, and will be back this week I'm told. Until then I'm a bit limited, since it gets the favorite station.)

> Whoa Cecil i dont follow that at all

Resonant passive elements absorb more power
than do non-resonant passive elements. Resonant
passive elements therefore dissipate more heat
than non-resonant passive elements.

With EZNEC, check out the feedpoint impedance
of a two element Yagi when both elements are
resonant Vs when one element is 5% longer and
a non-resonant reflector.

The following values are not optimized by any
means but will give you an idea.

With ten foot spacing between two 33 foot elements

The gain is virtually bidirectional at 10.7 dBi.
The feedpoint impedance is 20 ohms and the current
induced in the passive element is 0.84 amps.

Keeping everything else the same and adding one
foot to the reflector yields the following results.

The gain increases to 11.9 dBi with a F/B ratio
of about 8 dB. The feedpoint impedance is 30 ohms
and the current induced in the passive element is
lower at 0.75 amps.

Making the reflector non-resonant causes its current
to fall by about 0.1 amp thus reducing losses while
the feedpoint impedance has increased by 50% and the
gain has increased by 1.2 dB. There doesn't seem to
be any downside to non-resonant passive elements.

Every real world network contains both inductance
and capacitance. The circulating currents between
them are maximum at resonance, i.e. when the
reactances appear to disappear but they don't.

Depends to some extent on whether you are focussed on gain in the
desired direction, or rejection of unwanted signals, or a balanced
system assessment (eg G/T).

Stacking a pair yagis in one plane narrows the beamwidth in the
orthogonal plane... so if you stack two horizontal yagis above each
other, you achieve the gain increase by reducing the vertical
beamwidth without much change to the horizontal beamwidth or pattern.
The stacking distance influences the pattern, the location of the
pattern nulls near the main lobe, the magnitude of side lobes.

Obviously there are a bunch of mechanical / physical issues depending
on the required gain, and the stacked yagis requires a more
complicated feed arrangement which has additional loss which might be
significant if you were chasing best G/T ratio.

Wow! funny you should mention that! I lost mine in the same storm front here in PA. The antenna got whipped around so much that the fiberglass/dowel joint pulled through the drill holes, then finally broke the tubing, and down it came. I had some more tubing of the right size, so the fix wasn't too hard

> Has anyone used the Gap Challenger, compared to other verticals, and

I haven't used one, but a Ham I know has - and liked the Butternut a lot more. He's pretty knowlegeable IMO, but that's just one data point.

Designing an RLC circuit is trivial. The equations are simple and well known to any 2nd year EE student.

However, you need field theory and materials knowledge (among other things)to design an antenna.

If you design an antenna only looking at ohm's law, you will never be successful.

Re "it does not agree...".When you look at the main characteristic of a
yagi antenna which is the gain of the main lobe and then compare it
with the rest of the radiation field then I would say it is
inefficient. I sure wish I had a picture of all the radiation vectors
that go into the shaping of the field. I did a circular pattern array
the other day where a circular cone was radiated vertically and I
thought that was as close to a beam that I ever had seen but why it
formed that way is a mystery. Frankly I feel the major need nowadays is
a broard beam as possible for line of site use for wireless devices
where the gain is constant for excess of 90 degrees coverage plus
large bandwidth rather than a emphasis on gain itself

Ofcourse they are.They are both resonant and have the same "Q" which is
equivalent to half power. Isnt that why we talk of a half power width
of a main beam because of the assertion I just made. This is a
excellent candidate for a complex circuit analysis since the Q is the
same regardles of movement away from the resonant frequency and
coupling is not a factor!

We use a 4 over 4 array for 6m that I designed for the VHF contests.
The advantage for us, in the northern midwest, is that I was able to
make a relatively high gain system, 10.5dBd free space, that had no dead
spots in the pattern, as well as a main lobe that was over 45 degrees
wide at -3dB. The F/B is intentionally only about 18dB. It's nice to
have a pattern with no deep nulls in the midwest, because the signals
can come from any direction, and there are usually no, or few, big
signals to cause problems. We can also cover a broad area, easily 90+
degrees, during openings with the main lobe without turning.

On the other hand, if I was on either coast in a high population density
area, I would want a long yagi with as much F/B and F/S as I could get.

Whenever possible, you design and build what is best for your location.

Art:

If you refer to something that is "not in the books" one should take great care. Why I do think evidence can be brought out and can be demonstrated that some of the ways we "think" antennas are working is not real, however, great men have developed thinking models and formulas which are able to let us design and use WORKING antennas which are PRACTICAL. I site that mysterious 377 ohms as an example, or for another, incorporating the spin rate of the earth into antenna formulas (time), ridiculous (but useful!) But, those "old books" contain methods and means to develop antennas which do work and which do work well, we owe much to those who have gone before us ...

I am only hoping that by refusing to allow "magic numbers" to be embedded into equations without any suitable explanation of what those numbers are "REALLY ABOUT" will one day awake the man who can form the vision and see what the others have all been unable to, Tesla seemed to have had an excellent ability which I hold as example of the type of "vision seer" I mean.

I have an open mind, I guess you are as likely as the next guy to "be the one!" Never hurts to try anyway ...

However, thank God practical antennas work and we have the tools to design and build them.

Regards,
JS

I figure that if it works ok on my program AO PRO and it is then
checked out OK on NEC4
independently,and I can produce the electrical laws that backs it up it
will get into the books tho for the present time it is not there now.
For a very long time I have tried to introduce this and others to those
who are experienced in that sort of thing but I could never get it off
the ground because the thread kept on being changed to suit somebodies
whim or it developed into a name calling setup that it was impossible
to procede. Actually I let one patent application drop during the
examination process because of the badmouthing that I got but my back
is now stiffer and this one is going all the way. I do it not for money
reasons but because antennas is my hobby despite my so called lack of
knoweledge I have had patents during my working years at G.E. and other
places so the idea of patents doesn't carry much with me any more. For
all the experts we have had over the years on this newsgroup I have
never been able to thrash out one of my ideas to fruition because of
various nebulous reasons. If I brought one up involving SWR, coupling,
baluns e.t.c. the thread will grow by leaps and bounds in minuits
because everybody has something to say about it. If a subject is
brought up that one cannot provide insight then that person feels
denied that he cant post so he will resort to firing bullets and
stones.

I am considering purchasing a remote auto tuner for my continuing tinkering with verticals. My current focus is on 80-160 meters with 33+ foot verticals. The auto tuners specs claim a max inductance of around 32 uh. The tuners computed with the ARRL program TLW20 require much larger values of inductance.

Will the Auto tuner (SGC-237) that claims to match any wire greater than 28 feet long really do it?

I like the Hustler BTV line of verticals. Had my 5-BTV up over 2 years now
and it works a treat. Whichever vertical you settle on invest some time into
a ground radial system if it is to be a ground mounted antenna.

I have a SGC-230 (the big one) and an approximate 35' telescoping
whip on the R/rear of a 30' 5th wheel and it tunes fine on the lower
bands, including 160M. I have to shorten the whip up a bit to get it
to tune on 10M though.

larev wrote:
"I`ve heard the term 1/2 wave dipole with a balanced lead-in, but don`t know what that would look like."

It might look like two equal length wires supported end to end with insulators at each end and in the center between the two wires.
The balanced line connects in the center to the wires at each end of the center insulator. one line wire to one antenna wire.

The overall length of the two wires totals about 1/2-wavelength only at one particular frequency or wavelength. but it may receive well over a wide range of frequencies though it is resonant only at specific frequencies.

In 1938, GE sold a dipole antenna kit for its multiband home radios. This aerial kit was called a V-doublet kit. The two equal-length wires were to be cut to fit the user`s available space. The kit also included two high to low impedance wideband r-f transformers, one to use between the doublet and the transmission line and the other to use between the transmission line and the radio`s input terminals. The transnission line was a low-impedance twisted pair of insulated wires. The idea was that such a balanced transmission line is immune from noise pick up. Neither wire is grounded. Noise induced in both wires has the same magnitude but cancels in the receiver`s transformer input as it is flowing in opposite directions through the coil.

As I remember, it worked very well.

Best regards, Richard Harrison, KB5WZI

I once forgot to attach my bugcatcher so my SG-230
tuned a single four foot bottom section and reported
finding a match on 75m. The question is not will it
find a match but will it put any power into the antenna
at that "match" point - or is the tuner itself just a
dummy load?

Did you model the exact circuit of the SGC tuner? IIRC they use a
l/pi-l configuration and an autotransformer.

>Will the Auto tuner (SGC-237) that claims to match any wire greater
>than 28 feet long really do it?

The demands on the tuner will depend on how good a ground system you
build. If you use a poor ground system, a side benefit of the poor
efficiency is a subtantial amount of resistance in the feedpoint
impedance, though you are probably still looking at thousands of ohms
of capacitive reactance. If on the other hand you have an outstanding
ground system, the very low value of feedpoint R becomes challenging
for the tuner, and the efficiency you saved with the gound system
might be lost in the tuner.

Of course, the other option is to lengthen the vertical to raise the
radiation resistance so that it is not totally swamped by ground
system resistance.

Back to you question, will you get a match? If the tuner lives up to
its specification, you should... but you are looking at the world
through your VSWR meter, and that is a very limited view!

Owen

That's precisely the point. If you wanted to match a 30ft whip on the lower bands, and didn't have a tuner, you would be thinking about large air-wound base loading coils.

The small inductors inside amateur auto-tuners are nothing like that standard of construction, so the losses inside the tuner will be higher. As Cecil says, when a tuner is forced into a tough situation, its 'load' impedance may consist mostly of internal losses... and an auto-tuner is perfectly capable of matching that.

One of my prized possessions is a Racal military auto-tuner that is rated to handle 1kW continuously into a 30ft whip at 2MHz. Sure enough, it contains some very large air-wound inductors, with the kind of high-Q construction that you'd expect to see at the base of a mobile whip.

A really good amateur project would be to combine the smart controller of a modern auto-ATU with your own individual collection of large inductors, capacitors and relays. However, it would take some guts to buy an auto-tuner, remove all the undersized RF components, measure their inductances and capacitances, and then throw them away!

Jerry, if I came across a bit loud I apologize.. I usually skim down the latest chatter and then just post to the group off the bottom message, often having no direct bearing on the particular post it spins off from... Also, I skim a number of groups and topics and I run a business so I can miss a post that puts a different spin on things... If I ruffled your feathers it was not intentional...
Let me comment that I absolutely agree with you that claiming a Yagi is inefficient from the perspective of I2R losses shows a lack of basic knowledge... Having said that, let me also note that closing the spacing, i.e. tighter than the classical Yagi-Uda array, and putting the beam into Supergain territory has consequences... Moxon has a non mathematical discussion of the supergain antennas with a graph of spacing v/s gain v/s impedence, and I Krauss mentioned that he designed his flat top array stimulated from a paper by Brown (I think it was) where he discussed arrays that have more than additive gain by tight spacing... Anyway I digress; the point of all this mumble is that these supergain "Yagi" arrays can have quite high I2R losses... But the commercial Yagi-Uda today is not in that class...

Anyway, Cheers ... denny / k8do

That really would be great. I'm keeping that in mind for some day.

For a non-random-wire installation and not too many bands, you can go with manual switching of networks. When I lived in an apartment, I had a magnet wire antenna that consisted of two random lengths fed in the "middle." As such, every time the antenna broke and I put it back up, I needed a new match on each band. This is the kind of a situation where an autotuner really shines; I decided to use a remote manual tuner instead:

http://www.n3ox.net/projects/servo

When I moved into a house, I was able to put up something a little sturdier for the lower bands. Since it's always the same radiator and always the same ground system, I'm just using switched L-networks at the base to match it. It's 40 feet tall; the 80m matching network is a 20 turn tapped coil, #10 copper wire, about 3.5 inches in diameter. The other matching networks have air variable caps and 2" self-supporting #10 coils.

http://www.n3ox.net/projects/lowbandvert

John, if you're thinking of using a 33 foot vertical on 160,80, and the higher bands, might I suggest an approach where you use a GIANT tapped coil matching scheme for 160m, taps switched with a big relay, and then have relays to select whether you're using the 160m/80m matching network or the autotuner. For both of these bands, an inductor with the bottom end attached to the ground system with a tap near the bottom for the feedline and a tap up further for the antenna should work fine. It's basically an L-L step-up L network.

The autotuner should be fairly efficient on 40m and up, though you might want to add a few feet to the vertical to avoid the high impedance of a half wavelength on 20m, but I dunno.

It's really the bands where the vertical is significantly shorter than a 1/4 wavelength where you need a high-Q matching network.

Dan

3385. Speaking of I2R losses

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-04 14:07:44 UTC
From: Denny <k8do@mailblocks.com>
Message-ID: <1165241264.802879.295680@f1g2000cwa.googlegroups.com>
Source record: 48559

I am currently playing with tuners... Specifically link coupled... And I have been making my own condensers... Part of the exercise includes efficiency <'that' word again> of power transfer, more specifically tank coil losses... I had been using my fingers as my calibrated temperature differential meter but I have gotten the tuners engineered to the point where there are not enough differences to tell by feel... So I purchased an Infrared measurement gun...

<fascinating little instrument - did you know that on a clear day with the air temperature +12.1 F and zero wind, that a 5 foot diameter black rubber tractor tire facing the clear sky to the North can have a surface temp of -2.6 to -3.0 F? I didn't but that is what I found... OK, I digress again>

So, I have been running power soak measurements of the tuner components with the power source remaining energized during measurements - the nice part of a non contact instrument... The measurements turned up surprising results <to me>...
The continuous power level was 680 watts input to the tuner box at 3508 kc (two Bird meters, uncalibrated and the power averaged / 670 and 690 W. respectively)... The power soak time was ten minutes total... The outside air temperature was +12.1 F throughout the measurement period - mid day... The tuner components were +12.8 at the start (- + 0.2 F)... The tuner parts are in a plastic waste bin with the top on, except during measurements, to control air currents... The box sits about 4 feet away from the wall of a large building and shaded from direct sunlight <weak sun> at the time of measurement...
The coil is ~4" diameter and consists of 20.5 feet (22 uH) of #10 enameled wire wound on a paper mailing tube, and glued down with epoxy.. The link coil is the same wire (2.2 uH) wound on PVC tubing and slid inside of the tank coil tube - it was not available for temperature measurement, a finger slid inside of the PVC tube did not detect any temperature rise <power off!>... The tank condensers are aluminum and are ~24 square inches in area per plate (a pair of caps in a series tank configuration)...
At 5 and 10 minutes the top was popped and the surface temperature of the tank coil and condensers were measured - taking about 30 seconds - and the top replaced... The results for both times were within a few tenths of a degree...
The coil was found to be +12.9 to +13.1 F and the condenser plates were +31.5 to +32.3 F... A result which sent me away mumbling to myself... Not what I expected...
This is consistent with an earlier test in which the tuner was powered for 10 minutes at 1800 watts with the exciter sending dahs at 20 wpm (typical contesting environment)... The components were finger measured

<power off> and the coil felt to be barely above the starting temperature and the plates to be just a bit warmer than the starting temperature, which prompted the purchase of the infrared gun because it couldn't possibly be right - we all know that condensers are 100% efficient and coils are lossy - right?...

As others have noted, the auto tuners will have no trouble matching a 33 foot vertical on either 80 or 160 meters, even over sea water.

Using one at the antenna may reduce losses in your coax since the swr will always be low.

The auto tuners will introduce their own losses, as will any antenna tuners, although with shorter antennas the losses may be greater. QST had an article in which auto tuner losses and matching ranges were measured and I think compared with conventional tuners. If I recall, the results were less unfavorable toward auto tuners than I had expected.

To reduce auto tuner matching losses to insignificant levels, you might consider adding some lumped inductance at the base of your vertical (or even better, part way up as in center-loading). You can add a capacitance hat as well. If you cause the 33 foot antenna to appear resonant at either 80 or 160, you will see reduced auto tuner matching losses on both bands. Just a rough approximation to the required number of turns ought to work. You're only trying to provide enough external loading to reduce the tuner's losses. Resonance really doesn't matter much. If you do this, you should be able to enjoy the ease of QSY without a serious loss penalty and without a need to switch taps or retune manually.

Of course your 33 foot vertical resonant at 80 or 160 meters may not perform well at 40 meters and above, or worse, may not provide an impedance your tuner can handle at those frequencies.

Chuck, NT3G

Not a problem. When a half-wave vertical is fed against ground, the impedance is lower than many people imagine, and well within the efficient matching range of most auto-tuners.

When you're using an auto-tuner, your whole approach to antennas gets turned around. Just put up whatever you want, or whatever you can, and in most cases the tuner will take care of it.

At the old QTH, I had a 33ft pole which was guyed at the top, and had an auto-ATU and plenty of radials at the bottom. That simple pole worked well on 3.5-18MHz, and would work after a fashion from 1.8 to 30MHz. In addition, it could be tilted over quickly and various other add-ons plugged into the top.

The simplest was a 12ft fishing-pole extension, which favored DX on 3.5-14MHz.

Another configuration added a 30ft horizontal extension wire to make an inverted-L, about a half-wave on 40m and about a quarter-wave on 80m. That one was excellent for 80m DX, and quite usable on 1.8MHz.

For more serious 1.8MHz work, the free end of the horizontal wire could be very quickly lowered to ground level, and an extra 100ft of wire added. This gave a quarter-wave on 1.8MHz, and also an end-fed half-wave for 3.5MHz. It was good for local working on 3.5MHz because the high-current portion was horizontal at about 30ft.

I really couldn't tell you what the exact height and wire lengths were - whatever, the auto-tuner took care of it.

Good work. Congratulations on doing some real experimenting and thanks for reporting.
What do you attribute the losses in the cap to? Could it be contact resistance between the plates and the rotor? Would it be possible to substitute some commercial cap temporarily to compare?

Show me a 100% efficient cap first, then I will show you where to patent
it and sell it. You will then have the money to purchase my bridge in
the desert!

Of course, there must be lossless caps somewhere, huh? Because a cap with no dielectric would suffer no losses (ignoring the resistance of the plates to the inrush, exhaust of electrons), huh? So then, a cap consisting of plates in a vacuum would have no dielectric and no loss.

Strange, I seem to still notice a loss in such a device when examined mathematically. Perhaps the ether is serving as a dielectric?

I'd venture that the ground radials are more important than the antenna
itself. Not very glamorous perhaps, but critical.

Hi Denny

The fact is, I probably get "ruffled" too easily, probably because I'm insecure. I'm not the sharpest antenna designer around.
My way of antenna design relies mainly on actual, measured data, so I am a little short on convincing theoretical data. But, my approach to determining relative efficiency would be based on measured data.
If *I* had made any statement on the efficiency of *any* antenna, you can be sure I would include some measured data. Measuring Yagi antenna loss is probably too mundane for Art. He already knows things that would require me months of testing to 'check up on'.
If I wanted to know the "I squared R loss" efficiency of one antenna compared to another antenna, I'd need to conduct time consuming experiments.

Jerry

Cecil, I find that very interesting, my antenna is designed around
resonant
elements as you know which provides a more linear SWR curve which I
translated into less losses. I admit I never exceeded the yagi gain tho
I must admit I am pursuing the formation of other types of radiation
including circular When looking at different types of radiation as well
as making desired variables measurements move in concert with each
other so that we can diminish the compromises that come with untuned
elements.I have a lot of ground to cover

The autotuner at the feedpoint is certainly an interesting solution to convenient frequency agile operation.

The risk, as some have identified, whilst a match is obtained for the transmitter, and transmission line losses are low, that antenna performance (efficiency) may be lacking. You just can't tell by looking at the VSWR meter on the radio.

I put some notes together exploring models of an antenna system based on NEC models of the radiator, estimates of ground system loss, calculated loss of a practical L match, and calculated transmission line losses. There are three articles that may be of interest (John and others):

http://www.vk1od.net/NaroomaEFW/NaroomaEFW.htm

http://www.vk1od.net/InvertedL/InvertedL.htm

http://www.vk1od.net/multibandunloadedvertical/index.htm

Some have mentioned avoiding high impedance resonances as they will damage the tuner. Some of the articles above predict the voltage impressed on the tuner, and for longish wires, it isn't nearly as severe as using one of these tuners on 2.4m long mobile whip (as people do, and in compliance with the tuner user manual).

Taking a system view, all three of the articles show that there is a lower frequency limit to efficient operation of the antenna system, and the major contibutions to loss.

Ground loss is commonly the most signigicant element for minimal installations.

It seems obvious that in order to reduce ground loss, one should improve the ground system. Taking that system perspective, one of the ways (and it may be the best way in most situations) to reduce ground loss is to lengthen the radiator.

Source record: 48575

Well, there are dielectrics and there are . . . ummm well you get the point...

In this case the main dielectric of my condensers is glass, probably stannous float bath soda glass... 0.100" thick with an aluminum plate on each side... After my fingers had found the disparate temperature rise on an early test I did a literature search for the dielectric constant and loss factor of glass and discovered that not all glass is equal - or as Orwell put it, some of the animals are more equal than the others...

Anyway, Soda glass has a loss tangent of 0.01 to 0.05 and a dielectric constant of 6 - and Borosilicate glass (Pyrex) has a loss tangent of 0.001 to 0.002 and a dielectric constant of 4... So, it would appear that Borosilicate glass is better as a low loss dielectric... The trade off is that with 1/3 lower Dielectric Constant I would have to increase my plate areas by 1/3 to maintain the same capacity... The jury is out on this... 3.5 mc is relatively low frequency... I am not sure how much of the heating is due to the loss factor of the glass and how much is I2R heating from the current flowing across the plates... I spoze I could order some custom made 8" X 10" X 0.100" Pyrex plates and compare otherwise identical condensers... OTOH, I spoze some of the more equal animals in my house would complain over sticks and stones in their xmas stockings after I pay for the Pyrex...

Cecil:

What is the best fly wing scale you have?

I would think specs would call for one capable of
0.00000000000000000000000000000000000000000000001 gm resolution ...

Well, Santas coming, hang out a big sock!

Scratching head,
JS

>OK, I digress again>

It is not such a digression.

You should do make measurements of the temperature of different materials that you know are at the same temperature, and see what results you get from your non-contact thermometer.

The emissivity of the surface is an important factor that limits the absolute accuracy of these things.

It is an interesting experiment that you have described, though I am not sure that surface temperature (if it is accurate) alone is a good indicator of the power flow to the air. For example, would you expect that the temperatures of natural coloured and black aluminium heatsink to be the same if dissipating the same (non zero) power in the same environment? Extending that to your experiment, is dark enamelled copper wire (as may be used in a coil) a better black body radiator than bright aluminium (as may be used in a capacitor).

Art:

You are correct. I have always longed for a "proper" newsgroup for
these discussions, maybe:

rec.amateur.ridiculous.antenna
rec.amateur.unconventional.antenna
rec.amateur.alien-designed.antennas
rec.amateur.mystic-psychic.antennas
rec.amateur.opium-dreams.antenna
etc.

Only kidding a bit here, but who cares its name, I think it worth while
to strain the sands for a bit or piece of 'theory' which has been
replaced with a 'magic number', which some unexplored, or unused bit of
physics lies behind. One just gets used to using developed formulas and
terms and forgets to question where they came from ...

Indeed, I even suspect we may, eventually, discover time! However, our
earth spinning is NOT it! Nor, I seriously doubt, is the speed of
light, rather these are only two things subject to the "Universal Time
Frame."

At least we should be able to be rid of hecklers!

Regards,
JS

Hi SC,

Yup, I got my tech ticket a few months ago, and I'm now working on learning code and studying for the general ticket. I hope maybe January or February, but not until I can get my ham nook setup in the garage plus move my radio from the car to the garage so I can actually focus on the radio :) It's hard learning how to ragchew while on the interstate. hehe

I do have a C64 on the way, and that plus what I have now should be enough to get me going. Too much fun!

Take care,

Alex

And of course, the magnitude of the surface area over which the power is
being dissipated will also influence the temperature rise of the small
area being measured by the instrument.

Measured temperature differences of the same material and at the same
distance (under different experimental conditions) are likely to be more
accurate than absolute measurements with unknown emissivity.

I have a circuit in which there is a series capacitance of value 680 pF. The characteristic impedance of the line is 50 ohms. Can any suggest how do i plot the capacitance in the smith chart.

If suppoe it was a parallel capacitance, how do i do it?

I doubt this is a very effective communications channel for an
introduction to the Smith Chart, you need pictures.

Google for "smith chart tutorial", you will find plenty, and amongst
them you should find a suitable intro.

Owen's right. A picture is worth, generally, about a kiloword.

I'd also recommend you download one of the free Smith chart programs. You may also even find a decent web aplet that will plot directly in your browser window.

For a quick more direct answer: for a series capacitance, plot on the impedance grid. The capacitance must be converted first to a capacitive reactance: Xc = -1/(2*pi*f*C). That is the length you need to move along an arc of a circle passes through your starting point and is tangent to the unit circle at infinite impedance. You will see some of these plotted on an impedance grid; your starting point may already lie on one of the plotted ones. For example, if the chart is normalized to 50 ohms, the 50+j0 point lies at the center of the chart. Let's say that the starting point is 25 ohms, and the frequency is 9.36MHz. Then the capacitive reactance will move you counterclockwise (in the normal presentation of the chart) along the arc that passes through the 25 ohm point (or the 0.5 point on a chart normalized to 1 ohm), about 35 degrees, to 25-j25 ohms. That should not be a surprise: the reactance of the capacitor at 7MHz is 25 ohms capacitive; an impedance of -j25 ohms. Series impedances simply add.

For a parallel capacitance, find the suseptance of the capacitor at the frequency of interest, and follow a arc of constant conductance on the admittance overlay for the Smith chart. Remember, admittances of parallel components add, just as impedances of series components add. For the case in point, again at 9.36 MHz, you should go clockwise about 75 degrees along the arc of a circle which is tangent to the unit circle at impedance = 0 (infinite admittance) and end up at an admittance of 0.04+j0.04 mhos, or an impedance of 12.5-j12.5 ohms.

If you go back to the first example, with a series 680pF capacitance, and then add a shunt inductance, you will travel from the 25-j25 ohm point, counterclockwise along a constant conductance circle. If you make the inductance 850nH, you will find that you end up at an impedance of 50 ohms: you have matched the original 25 ohms to a 50 ohm system, at that frequency, with an "L" network. The Smith chart lets you visualize the match very quickly, once you are comfortable with it.

A computerized Smith chart made the numbers above much easier than the words!

Cheers,
Tom

Actually, unless the heat sink gets pretty hot relative to its surroundings, a large percentage of the heat loss is convective, not radiative, assuming we're operating in air at normal atmospheric pressures. It all gets much more interesting in a good vacuum.

If I got the numbers right, for example, blackbody radiation at 280K is about 35 milliwatts/cm^2, and at 300K it's about 46 milliwatts/cm^2. So 20C above roughly room temperature ambient gets you a whopping net 11 milliwatts/cm^2 to radiation. (Fins facing each other don't help radiation, but do help convection.)

Cheers,
Tom

Hi John

I didnt mean to imply that any antenna is 100 percent efficient. I would suggest that the amount of power lost to I squared R losses in a well built Yagi would be so low that they would be time consuming to evaluate.

I have even thought about how I'd try testing the I^2R losses in a Yagi, as compared to another antenna design. But, that would be long learning process for me.

I'd sure like to see Art's data before I'd start a test of yagi efficiency.

Jerry

(I apologize for not thinking of this in time to include it in my
previous posting...)

Remember, too, that what looks "black" to us in the visible spectrum
may be quite different over the spectrum including most of the
radiation, especially when the object is only about 250K to 350K. At
300K, the peak of black body radiation occurs at about 10 microns, less
than 1/10000th the frequency of visible light. I suppose heat sinks
are dyed black more because we think they should look black than
because it does any good thermally. And avoid buying heat sinks that
are PAINTED black; the paint just adds to the thermal resistance.

Cheers,
Tom

Shoot, make that "less than 1/10th the frequency of visible light," but still darned little radiated in the visible region.

There's cool 'speriment using a spherical flask of visibly opaque liquid to focus IR radiation to a point where you can feel it very easily. What you see in the visible spectrum isn't what IR "sees."

Cheers,
Tom

>
> If suppoe it was a parallel capacitance, how do i do it?

Hi Money

A purely reactive load, plots on the circumference (or perimeter) of the Smith Chart. It plots on the lower half (the minus impedance half) if it is capacitive, as in your case.

If you pick a frequency around 10 MHz, the capacitor will have close to 75 ohms X sub C.
Since you are working with a 50 ohm line, 75 is plotted on the lower half of the chart, at its perimeter and with a value of 75/50, or, 1.5 on the chart.

I really like getting help thru Wikipedia. If you read a few of their sites on "Smith Chart" and still have questions, I'd be happy to tell you what little I know about Smith Charts.

Hello friends,

If you need a new website, we are offering the best and most affordable services ever. Our new Website Builder tool will allow you to create custom designed, professional Flash websites in matter of hours...Check out our rates, as little as 12.95$ a month, on our website. No computer knowledge or experience is neccessary. No extra charge for domain registration, web hosting or computer support. Check out our packages starting at 12.95/month today!

http://www.MyBestDealEver.com (My Best Deal Ever.com)

thank you,

Dan:

I think we have arrived at the quantum/nano level here, you know, entangled particles, particles which can be in two places at once, particles which exceed the speed of light, it is a no mans land. Indeed, it takes guts to just attempt a discussion on the subject ...

We tend to think at large levels, wavelengths traversing long stretches of conductors, whole capacitor plates, etc. Naturally, even if one is stating correct facts on a quantum level he is going to called an idiot--if he attempts to even advance a theory which encompasses the above, who can resist laughing? None-the-less, it is true, the world of physics becomes upside down (apparently, with our present understanding.) Who can tell a "nut" at this level, everyone is going to look the same here. <grin>

Regards,
JS

> am allowed to
>

Hi Art

Show me some numbers and some data and I'll change my mind. I never said
that you were a blithering idiot. I am not qualified to make a statement
like that about someone I dont know. But, you do write alot of text in
which you apparently dont care about anyone being able to understand.
Blithering idiots do that too.
Please be aware, I really like real technical challenges that dont require
alot of theoretical math type proofs. But, when the challenge is to prove
you wrong (or right) about the "Efficiency" of a Yagi I'd anticipate there
would be some data (measured or calculated) coming from you. I havent seen
the data.

I too find it hard to believe that engineers (in general)need to read only
the first page of a paper in order to understand the entire text. I used to
work with alot of engineers. I really admire their ability to think
analytically. I consider engineers to be smart people , but reading only
one page of a mulitpage document then be sure the entire paper is trash. I
do believe that a perspicacious, experienced engineer has to be able to
perceive if the rest of any paper is worth reading if the first page is
written as though it was authored by a blithering idiot. Otherwise that
engineer could waste alot of valuable time.

I am not an aspiring HAM, but I once was. Now I'm an old, kinda
ignorant, HAM. They are probably quite similar. But, Art, I just have
alot of difficulty trying to understand your posts. Maybe you have a
"paper" that I could study. Tell me where I can read it. I still like to
learn new things.

My advice to you, Art, is Pay close attention to the advice of the
really good engineers that post here on this forum. If you cant identify
them, ask Richard Clark. He's one of them.

Hi Art

Since you top post I guess it is appropriate for me to do so also. I assume you make the comment about "fade away" without really expecting to do so. I still want to see data, any data that applies to your statement that Yagiis are inefficient antennas. As far as I know, you are correct about Yagi efficiency. I have been trying to understand how it can be determined that Yagiis are inefficient. At the beginning of this thread, I anticipated reading some data that I could understand. I have begun to think that data on Yagi efficiency probably doesnt exist. I encourage to show that I'm wrong about the data.

Source record: 48460

I was going through some FAA course material on Instument Landing Systems and the term SPACE MODULATION was mentioned several times. What the heck is this. From what I gather signals modulate each other out in space without benifit of any nonlinear device. I personally beleave this cannot happen but here is a reference to an FAA document.I assume they know what they are talking about.

Abstract : The report describes an investigation into the cause of incompatibility between ground and airborne measurements of VOR space modulation when using the latest flight inspection receiver, FA-4165:3A. The effort included a survey of the existing procedures and equipment used throughout the FAA, an evaluation of the ground measurement technique, and an evaluation of the airborne measurement technique. The result of the investigation identified problem areas with both the ground and airborne techniques.

I suspect that space modulation is more of a concept used to more easily understand/teach the operation of ILS systems and that actual modulation takes place in the receiver.

Hi Denny,

More fascinating was that everyone missed the significance of the
reported temperature.

>The coil was found to be +12.9 to +13.1 F and the condenser plates were
>+31.5 to +32.3 F... A result which sent me away mumbling to myself...
>Not what I expected...

OK, another surprise.

>we all know that condensers are 100%
>efficient and coils are lossy - right?...

Of course, and then the conversation went towards power factors and
such. Didn't Georg Simon Ohm die for all your sins, folks?

You need another specialized piece of test gear - in tribute to our
departed Reggie's folk-hero: a Kelvin Bridge Ohm Meter. Don't ask for
one at Radio Shack. When (and if) you get one, try measuring the
resistance of your home made cap (and I don't mean lead-to-lead, but
lead-to-plate, and for each plate, and for each lead connection).

For those who would press a Radio Shack Ohm Meter into this service, a
gratuitous -Chuckle-

Richard, I doubt many of us have to go buy a Kelvin Bridge Ohmmeter
from eBay to get what you're after.

I've got a Radio Shack meter with a 300mV scale; I've got a hefty power
supply with current limit, and I've got a 55 watt, 12V fog lamp. I'll
admit, I had to think pretty hard to figure out where I had a load
resistor to keep my power supply from going into overcurrent shutdown,
but it's on the premises, so it counts ;-)

I think I can do milliohm measurements of no more dubious accuracy than
the voltage and current accuracy of my Radio Shack meter in the
vicinity of 4.5A and 4.5mV

Long live four wire resistance measurements! Denny, I'd be interested
in whether or not lead resistance was a major loss component if you
want run a few amps DC through your cap lead / plate connection and
measure the voltage drop.

73,
Dan

Hi Jerry,

That, in fact, is quite very simple.

Allow that every living person on this planet (arbitrarily assign that number to be 6 Billion) has a receiver that is receiving you with arm chair copy (arbitrarily assign that to be 10dB over S-9) to your signal (arbitrarily assign that to be 100W) applied to your antenna (arbitrarily assumed to be a Yagi).

What is the Yagi efficiency?

S-9 is 50ï¿½V into 50 Ohms and through various mental gymnastics we can pin that down to being 50 picoWatts - but wait! There's 10dB more! call it ï¿½ nanoWatt....

Aggregate that over the entire Earth's total population eagerly awaiting the news of your power efficiency. 3W total absorption. 3% efficient.

Now, try something simple like raising that efficiency one notch, and still hitting ALL 6 Billion people.

Hint, the Yagi couldn't satisfy this in the first place because of a property called directivity, so a design that is "more efficient" is even more mythical ;-)

I dare say no one here can prove to be 0.001% efficient in these terms. [Must be validated through QSL cards.]

Efficiency: Can't live with it; Can't live without it!

Hi Richard

All kidding aside, I have actually learned things thru this thread. I had previously considered Efficiency to be a term applied to I squared R losses. Sure, I know about Aperture Efficiency, but I never knew about Beam Efficiency till someone presented a reference to a site mentioning it.

But, if that previous thread referred to a Yagi as being inefficient due to its I squared R losses, I want to see the data supporting that claim.

Incidentally, Pico Blvd doesnt go thru Watts

It is possible to get nonlinear interactions among electromagnetic
waves in plasmas, but you generally need very large amplitudes to get
nonlinearities to kick in.

I'm guessing that "space modulation" has something to do with multipath
reflections or something; the VOR signal that rotates is going to be
modulated by the buildings, mountains, and so forth around the
transmitter, generally, the "space"

Just a guess; I don't really know anything about VOR.

Felix,

I'm surprised over this test...

What you are implying but not writing is that your RoomCap doesn't work as well as an EH on 160m... I don't think that was what you intended... Hehe

Go home and do some basic math will you... The 160m EH need to be mounted 1/4 of a wavelength up while your RoomCap seems to be a vertical, able or even meant to be used from groundlevel...

If, as you claim, the EH is only 2 S units down? Wow! That's good - even absolutely bloody excellent! Well done EH! Unless the compared antenna is crap of course! And as I have not seen any building description on the RoomCap yet, who can tell...

If that EH where to be mounted at it's design height, you would have won at least 3 to 6dB signal strength, equal to 1 to 2 S units.

Also, the bandwidth of the EH suffers when mounted wrong (to low).

Why can't these testers RTFM before setting out to prove function or no-function of whatever gadgets they want to test?!
It's clearly stated about the mounting height!

However!!!!!

I'm very concerned over your statement about only one (1) S unit down if you rx/tx outside the EH design frequency (bandwidth).

My EH's (proper STAR's) are shortcircuits when outside the bandwidth! This is why they suppress TVI/RFI and harmonics in general as well as preventing the coax to radiate (one of the reasons anyway). If described in S units, the STAR is down 7 to 9 S units (well outside the 3dB bandwidth)if operated outside the bandwidth. It just goes quiet and the bandnoise just vanishes - exactly like the shorted coax it just became...

You just told me the 160m EH you tested radiates from the coax?! As you only had 1 S unit down outside the bandwidth. Bad bad bad! Was that an EH at all?! Or just a short fat dipole?

And guess what... All the EH documentation are available on the net for hams to try... without charges and fees...

Source record: 48470
Body handling: HTML body converted to readable text

In my usual habit I'll reply off the bottom of the que... Lots of good comments and suggestions...
In no particular order:
I suspect the surface of the black tire had cooled below ambient by convective radiation... Happens to my windshield on mornings above freezing ambient whilst the windshield will be a skim of ice...
Though the thought of what the tire might read under non-convective conditions occurred and was duly filed away in that great container in my head for further inspection... Actually I use the Rubble Method for filing information.. That is everything in my head is tossed on a great heap of rubble, and as I stir through the pile looking for one item, interesting bits of flotsam and jetsam flow back to the top of the heap for inspection, "oooh ya, I remember that!"

Yes, the thought that there might be unwanted resistance in the connections to the condenser plates occurred and remains to be investigated... The connecting wire is the #10 magnet wire forming the coil and is firmly bolted with #8 brass hardware and flat washers to a 1"x1" tab formed on the edge of the plate when I cut the plates from a sheet...

For Yuri, congratulations on the CQ160 win(s), nice job my friend... Drop me a description of his antenna setup... Wanna be's like me are always looking for an edge...
On the IR gun, it was in the ~$65 range on sale, as their economy model, I don't remember who the internet vendor is, I can get you the make and model if you need it... But just do a search, lots of sources and prices... The little bit I have used it I have been satisfied with the readings - nothing rings my 'no-way, Jose!' meter, so far... The 35' long radiant tube heater in my shop shows ~375-385 F at the mid point from 8 feet away, which is about right as it will not ignite paper on contact though it makes it brown - paper has an ignition temp of ~454 F ... The gun has a
laser spot so you can see where the detector is aimed and the size of the spot is proportional to the area being measured at that distance...

I suspect that dielectric loss in the soda glass is the prime contributor to the temperature rise on the plates... There is a significant amount of joules passing through the glass as strain in the dielectric..

Oh yeah, the question on the type of glass... Bad habits as an old lab rat surfaced when I wrote that... Common window glass is float formed on molten tin, and that is what my old chemical stained brain popped

out as 'stannous'...

On differential IR readings from the surface of various materials - well I can't say for sure as my credentials in thermodynamics are shaky at best (picture me shuddering in pain at the memories of Schrodinger equations and those IBM punch cards we used to program the computer in the physics lab 40 years ago - 'the horror, the horror'..... But, all the materials in the tuner were within a few tenths when at ambient, so I have no reason to suspect a gotcha when midly warmed...

Hi Art,

I don't want to get into the details of your new antenna concept.
However, consider this.

Your antenna, whatever it is, seems to be modeled correctly by both AO
Pro and by NEC4. Both of those programs are based on completely
conventional electromagnetic theory that has been in use for over a
century. In that case it is most unlikely that you have discovered any
new electromagnetic science.

It is quite possible that your antenna configuration is novel, and it is
even possible that your method of informally describing the antenna is
new and useful. However, new science it ain't.

No, I know it has nothing to do with things like that,it is as described in
the FAA lit a normal process of forming the ILS radiation patterns and
applies to VOR, Glide slopes and localizers. Google doesnt help much on the
subject.and I ve gone thru the indexs of about 20 radio and antenna books
without finding anything on it.

Wow! EZNEC average gain test shows +18dB... lessee... that means it's
about 630% efficient! Good work!

Space modulation, in the case of VOR, is produced by a dipole
rotating at 1800 rpm. The rotating dipole pattern produces a
30 Hz amplitude modulation of the VOR omni-directional
pattern. This rotating pattern provides bearing information
to the receiver. The reference 30 Hz is provided by
FM modulation of the omni-directional pattern.

Jimmie:

Just having a bit of fun. I am only familiar with "space modulation" when it comes to modems, as much data is contained in the key off mode, and the length of time key off occurs, as in the key on condition and its length of time (at least in one method of data transfer I am familiar with.)

Whether there is any relationship of one to the other is a mystery to me--like I said, just poking a bit of fun.

The circuit is actually an impedance transformation circuit to match it with line impedance 50 ohms. the frequency of operation is 900 MHz.

With a software i matched an amplfier circuit with line impedence 50 ohms. 680pF(series capacitance) is part of the impedance transformation circuit. I do get the point of traversal in a smith chart. For series capacitance i need to move along the constant resistance circle anti-clockwise.

But if i use the formula capacitive reactance = 1 / C W then normalise it to 50 ohms i get negligible reactance of 0.05.... Is it correct?

Yeah Jerry..... I have seen Wikipedia. :-) But from where did you get
75 ohms X sub C.... Wat does it mean?

Converting 680pF series capacitance to capacitive reactance we need to
use Xc = 1 / CW.... Is it not??

>
> Cheers,
> Tom

Yeah Tom..... U r right.... i get it. If its a series capacitance we have to move anti-clockwise along the constant r cirlce. So first all we got to do is convert 680pF capacitance value to reactance. As the frequency used is 900Mhz(RF range) & the line impedence is 50 ohms how do we proceed....?

Do tell if i am wrong.....
we know that Xc = 1/Cw .So we get Xc=0.26 . we need to normalise this reactance value. so divide this value by 50. we get 0.005 . But this is a negligible value, is it not??

I know how a VOR works its the concept of space modulation I dont
understand. How can radiated enery from multiple sources combine in space
and modulate each other. This is as described by the FAA manual. I am
thinking this can nit happen but the modulation takes place only in the
receiver, not out in space as described by the manual.

Art:

Lighten up. I am not afraid to be termed a "nut", if there is some sort of evidence there is something which needs to be looked at, discussed, thought about--I'll be right there up to my arm pits.

The nay sayers, those who claim everything has already been discovered, those who claim we already have all the answers and all is understood--they stand as chaff in the wind to me.

Many you deal with here are technicians. They are well versed in standard formulas, techniques and methods. I hear them saying, "If it ain't broke, don't fix it!" To a certain extent, they are quite correct.

Thinking is just a hobby with me, as is amateur radio and electronics.

I work in software for a living, thinking out of the box is a not a luxury here, it is a requirement. Unless there is good reason you do something unique/different/quicker/shorter/more efficient/more compact/etc. they will hand your job to china or india!

Take all I say with a grain of salt ...

Regards,
JS

Yes, right. It is a very small reactance at 900MHz. In other words, I assume it is just a DC blocking capacitor, if it is part of a properly designed network. It must be other parts which are doing the actual matching job.

Do you know the impedance of the port which you are matching to 50 ohms? Or do you have the network already, and you want to "reverse-engineer" the circuit to discover what the impedance is that is matched to 50 ohms?

I would expect that parts used in a 900MHz matching network would be in the range from perhaps 0.5pF to 10pF--maybe a little beyond, and also inductances in the low nanohenry range. And such small capacitances and inductances can be even small copper areas and short, narrow traces on printed circuit boards. Often it is better to analyze everything in terms of transmission lines, instead of discrete capacitances and inductances, when you are operating at such high frequencies.

Cheers,
Tom

> 75 ohms X sub C.... Wat does it mean?
>
> Converting 680pF series capacitance to capacitive reactance we need to
> use Xc = 1 / CW.... Is it not??

Hi money
```

I got 75 by making a mistake. The 680 pF capacitor will be about 24 ohms capacitive reactance at about 10 MHz., ?right?

When 24 ohms of capacitive reactance terminates the 50 ohm line, that impedance is shown as R0-J24/50, which is found on the perimiter of the chart. All impedances with R = zero are located on the outer perimiter of the Smith Chart. Find the point on the chart where -J 0.48 is shown. That point is in the lower left of the chart, when the chart is positioned so the purely resistive axis is reading left to right.
So, that answers your original question "how do I plot xxx". I asummed that you were aware that you cant actually plot capacitance on a Smith Chart. The Smith Chart identifys only Impedance. The Smith Chart identifies *all* impedances that have a real R value.

In 1966 I wrote a short article on matching with a Smith Chart for Electronic Design. It isnt worth much by today's standards. But, I'd be happy to send you a copy if you are interested in using a Smith Chart for impedance matching.

Glad you found it interesting. If you need to know more of the
theory behind the Smith Chart I would recommend
"RF Circuit Design" by Christopher Bowick. It is available
on www.amazon.com for $26.37. The treatment is fairly non-
mathematical, but it does give great insight into how the Smith
Chart works.

I don't know if the term Space Modulation is applicable to this effect, but the ionosphere does cause AM modulation.

The atmosphere from sea level up to approximately 300K feet altitude is an ionized thickness. This ionization peaks at the Paschen altitude of around 200 Kft. The ionization source is the sun. We see this with xray flares and proton effects [northern lights] and the loss of HF propagation. The lowest levels have little ionization [C layer, D layer, etc]. At xray peak fluxes we experience total loss of HF propagation and high absorption of 80/40 meter ground wave signals.

This ionization is not uniform nor is it static. It is quite dynamic and varies with air density [wind, rain, snow, etc]. The variation in ionization causes amplitude modulation of signals being propagated through the ionosphere. We normally experience it as QSB on HF and as flutter on some over the horizon VHF AM signals [not aurora related].

I had the bad experience of the modulation causing a false trigger in a flight test vehicle. We had about 5% AM on a near earth telemetry signal. We had to redesign the detector circuits to accommodate the effect.

Aircraft communications is AM and VHF. I assume, if this effect is Space Modulation, that it becomes important on weak signal paths.

Hi Frank,

Why is it that when people develop electronic implementations of the
Smith Chart (like this one) that they don't implement things like
complex Zo and attenuation in transmission line elements, complex
reference impedance (incorrectly termed Zo in this prog)?

3484. Simple AM Loop Antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-05 22:17:18 UTC
From: Bill <Me@bellsouth.net>
Message-ID: <Xns9890A52D83B20Mebellsouthnet@216.77.188.18>
Source record: 48507

Hello everyone :) I am looking for detailed plans for an AM loop. I will be using it only for one frequency 1370AM so I dont want any tuners just a simple AM Loop antenna for my AM radio. I will have to solder a 1/8 plug to a 6-8 ft feedline to connect to my radio. It is a Kaito portable model 1103. I want to built this AM Loop cause I listen to talk radio alot and the static and other distant stations sometimes make it hard. I have done alot of looking around on google searches but have found no real detailed plans I am not sure if I should go with edge wound or Spiral wound. Any info you guys can give especially a detailed plan would be greatly appreciated. or maybe there is a website I may not have seen you would like to suggest. I am sure I have seen most of them atleast the most popular ones. Anyways thanks in advance for any input:) Bill

Hi Owen,

Yes that has always bugged me. Not so much a complex
Zo, but transmission line losses would be nice.

Yes I have lol :) The station I am trying to recieve usually comes in pretty good but sometimes at night it gets noisy. It is my understanding that an external AM Loop antenna will recieve better than an internal loop that comes with a small portable. I also have heard that a Loop picks up less noise than an internal ferrite loop or random wire would. I have heard that these external AM Loop antennas used to be quite common in the good ol' days. But that they fell out of favor with most people to be replaced with the internal ferrite loopstick antennas. If anyone has some detailed plans for these older styled external AM Loop antennas I would really like to get ahold of them. Thanks in Advance :) Bill

Hello Bill,

Try -
http://rffun.com/catalog/mwant/4316.html

Variable caps are getting hard to come by, so a $49.95 to $59.95 price
for the completed project seems very reasonable. I purchased one of
these for my step father and it works great. You probably will not need
a direct connection to the radio, just place the Select-A-Tenna next to
the radio.

If you are determined to build one (as I was), just google
"AM Loop Antenna"
Lots of great articles out there.

Regards,

Christopher Cox

Source record: 48521

Thanks for the input Christopher :) I am indeed determined to build one. I don't want to build a tuning one though. I am more interested in a simple AM Loop that just connects to my radio to pick up AM broadcast. These use to be popular. I suppose it was when radios first started to come out. Anyways like I said they eventually were replaced by internal Ferrite loopsticks. I suppose people did not like these big ugly antennas on top of there radio. I don't think these old AM Loops had Tuners. And I think they may have been spiral wound. You connect the 2 wires from the antenna to the screw terminals on the back of the radio. But in my case I would have to connect an 1/8 plug to plug into my Radio. I have no idea what the size of the frame would be? How long the wire would be? and how many turns around the frame to make? I have searched Google and have not found what I am looking for there. I have found a couple of books but can't afford the price tag at the moment. I don't even know If the antenna I am looking for is even in the book. Here is a link to a few I have found if anyone is curious.
http://www.universal-radio.com/catalog/books/0016.html
http://www.universal-radio.com/catalog/books/3113.html
http://www.universal-radio.com/catalog/books/0533.html
If anyone else has any suggestions I am all ears. Or if you have any of these books and could comment on it. I appreciate it.
Thank You Bill

If you want to improve efficiency on 160m, think about raising the
radiation resistance and / or reducing the earth loss.

Possibilities to raise Rr include inductive loading high up, longer
radiator, capacity hat, more than one of the above.

Hi Bill

I built a couple AM loops last year. One is 4 feet on a side and the
other is 2 feet on a side. Both are made from PVC pipe and "hook up
wire". I can send you pictures.
If *I* was involved with the project of building this loop with you, I'd
sure try to get you to make tunable. Both of my AM loops are very sensitive
to getting the capacitor adjusted properly. I have connected the loops to
the receiver with two parallel wires from the antenna to the receiver.
That seems to work OK.

There is lots and lots of instructions for designing and building AM loops
on the Internet. From what I read, you are mainly interested in building
just one good antenna. You may not need a book for that.

3502. OE-254 Versus COM-201B Antenna Comparison

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-06 03:29:56 UTC
From: Anthony Jocius <ajocius@insightbb.com>
Message-ID: <4aGdna5-0bSopOvYnZ2dnUVZ_qKdnZ2d@insightbb.com>
Source record: 48376

I didn't know where to go to answer this question, so that is why I'm in this newsgroup. Basically I'm a reservist for an Engineer Command. Recently, my boss asked me to do a comparison between an OE-254 (standard 30-88Mhz mast antenna) and an Atlantic Microwave COM-201B (30-88Mhz mast antenna). Both FM antennas reach to about 42 feet. The COM-201B touts all kinds of advantages, but in my limited knowledge of antennas the performance aspect seems to me to be the same or very close. My biggest concern is durability. The Army for years (over 20) relied on this antenna (OE-254) and opting for a different one, with limited numbers scares me. If I could do a blanket purchase for all of our units, even those that already have the older antenna, I would opt for that. But with different antennas co-existing, with different parts etc, I'm very reluctant to make the switch. Can someone do an educated comparison between these two antennas? A study at http://www.gordon.army.mil/ac/Winter/Winter%2002/USMCnet.htm seems like an ad, instead of a fair comparison.

Brilliant! Why didn't I think aboutit?
Can you picture stupid hams paying crazy money for bunch of fiberglass fishing poles, some metal tape and stepping motors with controller that could be replaced by the strings. I was going to put up 6 stepIR, now I will save hugh money.
Where do I send the money?

Go ahead and build a tuneable one. It's not _that_ more complicated.
Besides, the minute you would finish your no-tune antenna, Clear Channel
Communications will buy up your favorite talk station and convert it to
country and western. Then you'll have to look elsewhere up and down the
AM band.

Thanks Frank, I thought the FM modulation was caused by doppler shift as a
result of the antenna rotation

I think just about anything is better than the ferrite antenna in most AM
BCB radios.
When I was a teenager the local 5KW radio station would go directional and
reduce its power to 1kW. When it did this I could barely pick it up.
Five miles down the road it boomed in. Unfortunately this was also the time
it started the programing I enjoyed. I already had 4 hooks in the wall
roughly in a square so I drped some antenna rotr wire arounfd the hooks and
connected the ends together to form a coil. From the two open ends I ran a
coax to a two turn loop i slipped over the ferrite antenna. worked like a
champ not to mention it allowed me to pick up a lot of other radio stations
from my South Ga.location including WLS with John "records truly is my
middle name " Landecker. After being able to pick up WLS I soon lost
interest in the local station.

Anyway this was probably not the best antenna but it did the job.

I always looked at the SteppIR's and thought they were pretty much
exactly worth the money.

By the time you worked up your own SteppIR-like control system and
actually got the sliding contacts to work in a low loss, reliable
fashion, you'd easily be up to the price of those antennas.

Felix:

Personally, I have a use for a small antenna. One which I can chuck into my trunk and take along on quickly planned days away in the wild. I have used the EH and got it up to good heights using a cord and slingshot. It is not an efficient antenna in accepted terms. The good match it provides over a good bandwidth and small size makes it perfect for some of my adventures though. Hoisted high in a tree at the 11,500 ft elevation makes it look good to me; good to at the 9,500 ft elevation while I fly fish mosquito lakes and have a bit of chat. Efficiency is in the eye of the beholder.

Put paying for a CD to show me how to build another of these "dummy load antennas" just doesn't float in my book ...

Could be the antenna was coupled to the radio by just wraping the coupling
coil around the radio. I forget which way worked the best now.

Hi guys,

I've been reading up on the different types of radio waves etc and am getting really confused between the concept different wavelength waves travelling different distances before being attenuated etc.

The more I think about it all the more confused I am becomming and I was wondering if someone would be able to help me with this....

Basically I have been told that shorter wavelength waves attenuate and scatter more easily. So working on this principle I know that medium waves (MW eg AM radio) are longer in wavelength than VHF (ie FM radio), so why is it that in car parks etc (i.e. under a roof) you can still pick up FM on the radio but not MW. Surely FM being shorter in wavelength (and consequently higher freq) will be scattered more? Is this to do with diffraction instead? Longer waves diffract more readily, so as FM is longer it diffracts more and is therefore heard 'around corners' (sorry for putting it like that!), whereas MW would not be?

So, shortwave is also longer in wavelength than FM so perhaps this is better for transmitting over long distances ie for international transmission, but MW is even longer in wavelength so why is this not used instead?

Lastly, SHF and EHF are used for satellite transmissions, but these are very small wavelengths for radio waves so surely here the scattering and attenuation would be so large that this would impede its path from the satellite to the ground? Or again are we just using SHF and EHF as diffraction effects would be minimal?

If anyone could shed any light on this topic for me it would be really appreciated.

Cheers

DC

Hello Bill,

Regarding your AM loop antenna.

Are you sure the external antenna socket also works for AM? You may
check this by inserting a plug without antenna. The ferrite antenna in
your radio will not be that bad.

You mentioned static and other distant stations. I am not sure whether
the loop will improve the reception. Has the signal from your favorite
radio station sufficient strength (on your current radio)?

Before you build, try to locate (with your current receiver) the best
place and orientation for your loop to be built. Do not use the
external adapter for this. If you cannot find a place/orientation with
good reception, a loop will not do much better.

If you found a good place, power your radio via the mains adapter. This
will clarify whether noise from the mains enters the ferrite antenna.
If so, the loop design must be such that noise does not reach the loop
via the cable between the loop and your receiver.

Generaly a loop will only help to overcome the radio's internal noise
(bad Sensitivity) and spurious products (generated by your receiver)
and interference from nearby sources (electronic equipment). The last
item only, when you can position your loop away from any interfering
source.

The loop will also not improve interference from a very strong adjacent
station. You may orient the loop to get a strong adjacent station into
a null, but this is possible with the built-in ferrite antenna too.

Regarding tuning.
With average means, a resonating (=tuned) loop can be made smaller and better. When you use fixed capacitors for most of the required capacitance, you may use a smaller (mica compression) trimmer capacitor to do the fine tuning to your desired frequency.

I hope this will help you a bit.

Best regards,

Wim
PA3DJS

3515. Stub Matching software ?

> ahold of them. Thanks in Advance :) Bill

A friend of mine makes them. He uses the variable capacitor
out of old AM radios. He winds a number of turns of #30 wire
on a one foot diameter round piece of Styrofoam. He first
determined the number of turns needed by GDOing the coil
and cap in parallel to about 550 kc. Seems to me he used
20-30 turns. Just sitting it close to the radio and tuning
it to resonance solved his reception problem. It was resonant
and directional and its field was all the internal ferrite
loop antenna needed in his case. CCrane sells similar loops
under the trade name Select-A-Tenna.

Anthony,
Dennis O'Connor here... Ham radio operator, used to be electrical engineering guy for General Motors, and a good judge of beer and beautiful women - so my opinion has to be right on, right?

All joking aside, I see nothing in the article that rings my BS bell... Looks straight forward... the radiated pattern claims shown on the graphs look reasonable.. The L-match at the input (the inductor and capacitor) is a standard circuit that is done for matching a radio to an antenna...
There is one point I would make the manufacturer clear up (and it is obviously a typographical errer).. The frequency shown across the bottom of the graph labled "Comparison of Tune COM-201 vs. Untuned Antenna", is clearly wrong... The axis is labled as representing MHZ (1 million cycles per second, i.e. 1,000,000) but the numbers are entered as 0.03 to 0.09... If you multiply 0.03 X 1,000,000 you get 35 KHZ (35,000 cycles per second) not 30 MHZ (30,000,000 cycles per second), and likewise as you move across the bottom of the graph from number to number... Again, an obvious typo but when they are trying to do Mil-Spec business, details count...
The thing I cannot judge from the write up is the mechanical structure... It sounds good from the write up, but you might want to actually look at one and see if you feel it will hold up mechanically in the tender hands of a bored recruit... Certainly a smaller parts count means less chance of missing parts...
All in all, it looks like a good product for your use...

cheers ... denny / k8do

Bill,

I have built a number of small receiving loops, and they all work very well. The easiest way to design the loop is to use a small (and free) program written by Reg Edwards. Go to his website (http://www.btinternet.com/~g4fgq.regp/page3.html#S301%22) and download RJELOOP3. It will give you all the info you need, including the approximate capacitance to resonate the loop. The basic loop consists of about .1 wavelength of wire for the highest frequency of interest. A larger loop with fewer turns is much more efficient than a smaller one using more turns. You will need a variable cap to determine resonance - the thing tunes too sharp to "cut and try". Once the cap value is determined, have it measured and make up a fixed cap if you really don't want to use a variable. You can use a single turn of wire around the main loop as a low Z pickup that won't excessively load the main loop, of come off the cap directly to a hi Z FET amp with a low Z output to the radio. That makes tuning really sharp. These loops have very sharp rejection, but work best during the day. At night, there are often too many interferring stations, but it's still worth a try.

I've done something similar but simpler.

I took two 20' Bream poles & mounted them on a 1"x 2"x 8' with clamps. I left a 4' gap between the ends of the poles. Total extended length = 44'.

I then strung #16 wire along the outside of the entire length, feed it with ladder line thru a tuner & mounted it on a 30' tower.

Walla, a rotatable dipole for 40 meters thru 6 meters (75 meters is a push but it loads).

It has gain & directivity on 20 - 6.

Total cost - less then $40

Bill,

Forget about the antenna problem. The bigger challenge is distinguishing
talk radio programming from static and interference, even if the radio
reception is perfect.

Bill,
Make your loop tunable. Variable caps aren't that hard to find.
Find a program to calculate the inductance of an inductor.
Try a google search of Reg Edwards, Reg is no longer with us but
his wonderful programs are still available.
(Someone else may want to post some solenoid inductance calculators)
Make an inductor of 240uh. (Yes, other values will work)
A pure 240uh inductor and a 56pf cap resonate at about 1370khz.
(no inductor is pure, your inductor will have interwinding capacitance,
maybe 15pf, so 56pf minus 15pf is 41pf) So 41pf would make it resonate
at 1370khz. (pf = picofarad)
You could use a 100pf cap that will tune from about 1000khz to almost
1600khz.
Using a 365pf cap, this will tune almost the entire AM band.

Make an inductor of whatever size you are comfortable with 1ft to 8ft.
(Rotation is important but once you find the direction that minimizes noise
for your one station you have it.) So if you have a wall that is oriented
correctly
you could string wire around the corners.
You can go simple, as in wind it on styrofoam or a carboard box or spend
time
on a good frame and base and easy rotation.
If you get this far then there are a few ways to couple the signal into
your radio.
Tell me what you don't understand and I'll do my best to inform you.
Mike

Personally, I love talk radio. I have, long ago, given up on getting
any real information from major networks ... but then if I had to
listen to rush, or chaps like him, I'd abandon talk radio also!

A tuned loop is the way to go. The only real practical application of
one needs a variable cap in my humble opinion ...

Hi Bill,

Give it a try. It may work for what you want it to do, but if you add
a capacitor, it will do considerably better. Also, claims of
canceling noise are rarely demonstrated without care and attention to
design (this one does not go that extra mile).

Bill:

Forgot to mention, it was for 10 meters, monopole.

Been considering a 160 meter dipole. Probably need some help getting
"materials together" and construction with that project (most likely
take a few days.) I am just beginning the math to figure out how many
36 packs I will need.

I expect it to be more efficient due the new fangled aluminum cans and
the expected lower losses in dc resistance!

Arie,

The versions of NEC that I have used all treat transmission line elements defined as such as lossless, and so the results will be in error to some extent, depending on the scenario. Allowing for that error, models I have built and checked appear correct.

The spreadsheet by L B Cebik linked from the page above depends on an assumption that Z is real for some of the match types, and again assumes that the line sections are lossless (implying Zo is real).

The assumption of lossless lines might often be acceptable for open wire lines, but less so for common commercial coaxial lines.

My experience with stub matching is that significant trimming of the theoretical design is usually necessary. I suspect tolerances of transmission line parameters is a large contributor to the error, and some stub designs become extremely sensitive to small changes in components. Assuming that stub matching is 100% efficient (ie that line sections are lossless) is another significant contributor.

>Does anybody know a source for (similar) stub matching software
>(freeware or evaluation), so I can check where things go wrong ?
>

The line loss calculator at http://www.vk1od.net/tl/tllc.php will calculate the transformation in series line sections of about 100 common line types, having regard for line loss. Impedances are dealt with as complex quantities. This also allows calculation of the input impedance of an o/c or s/c stub by specifying an appropriate termination impedance. The line loss model used is described on the page above.

For example, what is the impedance of a quarter wave stub of RG58C/U at 14MHz? You know it cannot be infinite, but that is what lossless estimates will produce. The calculator above suggests that 3.53492m of Belden 8262 s/c stub has an input impedance of about 2300+j0 ohms. At 7MHz, the same stub would have an input impedance of about 2.3+j49.96 (a quite lossy equivalent inductor) where lossless estimates would suggest 0+j50.

A useful feature of a "Smith chart program" would be a decent transmission line loss model for transmission line segments. Most that I have seen seem to ignore it, Winsmith allows specifications of line loss, but it is tedious and nevertheless only allows specification of real values for Zo.

XLZIZL and the derived TLDetails are applications that consider the line loss in calculations (but whilst estimating Xo, assume that Ro is equal to nominal Zo). There are other programs that use a similar approximation but seem to have unrealistic built in line loss data.

Just working the example of Bramhams solution in LB's spreadsheet with
http://www.vk1od.net/tl/tllc.php :

Line 2:
Belden 8262,
length=0.848*0.66=0.560m,
Zload=50+j0,
Zin=58.34+j20.44

Line 1:
Belden 9204,
length=0.848*0.66=0.560m,
Zload=58.34+j20.44,
Zin=75.22-j1.33

Seems close enough!

Which match type did you have problems with?

>Basically I have been told that shorter wavelength waves attenuate and
>scatter more easily.

Hi OM,

As a generality, this is true; but generalities that are this
all-encompassing don't actually explain anything. Scattering is
dependant upon what is doing the actual scattering, and this
dependency is related to its size in terms of the wavelength.

>So working on this principle

This is your first mistake because the generality is NOT a principle.
We will skip the remaining presumptions.

>If anyone could shed any light on this topic for me it would be really
>appreciated.

Light (as in illumination) will serve this purpose too, because it is
shortwaved (by a million fold or more) and yet it confounds many of
those presumptions that I discarded above.

Attenuation can by one of two ways. The energy can be consumed along
the way, or it can be diverted (scattered) which to the observer
amounts to the same thing - less light (or RF or waves or
what-have-you).

Scattering is a little more sophisticated in that the path along which
the energy was directed, changes (and sometimes, so does the
wavelength). Scattering will also offer other opportunistic modes
such as diffraction, reflection, refraction (a whole list of shuns).
You should note that a partial reflection of light, to the observer,
will appear to be attenuation. Further, through diffractions the
original wave may appear to become multiple sources of the same
energy, but with different phases. When those phases combine, the
observer may yet again perceive an attenuation.

To tie this all together, wavelength will determine if the scattering
body is suitable large/small to lend an effect to the observer. This
is why through your list of wavelengths there appeared to be unusual
distinctions. Those distinctions were the properties of the medium or
the interfering bodies (scatterers) - not the source wavelength, per
se. These properties fall into the studies of chromatography,
spectroscopy, and so on (which have their equivalents at all
wavelengths, but are suitable more for the optical wavelengths).

One excellent example is in the InfraRed region where water vapor selectively scatters, absorbs or transmits various wavelengths in a small band of frequencies. Water vapor will also do similar tricks in the 2GHz region.

ok, if i am reading this right the elements are stacked vertically above and below the fed element?
assuming the distances are in inches, your element 5 is about 5" from the fed element? and elements 2 and 4 are about 8" apart??

assuming the above is correct, you have probably rediscovered the hazards of runaway optimizations. aka: how to get super gain without really trying!
you will most likely find that the bandwidths are unusually narrow, and the feed point impedance is extremely low or highly reactive... all signs of a design that can't be fed without extremely high losses... and would only work on one frequency, if at all.

For reception you can get those little tuning caps they use in
the portables -- about 1 inch square and half an inch thick.
You can usually find them at Radio Scrap -- er Shack.

Hi Dave,

Super gain? I improved the gain and the feed Z by throwing away 4
wires. I hope "AO program by Beasely" is not slurred by this example.

>> Center Frequency of use 14.25 MHz
>> element length height
>>
>> 1 209.46 927.1 feed element
>> 2 198.25 973.97

>> 5 185.53 922.4
specification for a classical waste of time. [However, it is
certainly the poster child for first establishing a reference against
which improvement is measured.]

"DC" wrote:
"Basically I have been told that shorter wavelength waves attenuate and scatter more easily."

That is only part of the story. To pass through an opening, the wave must be small with respevct to the opening to avoid severe attenuation. An example may be evident when you are tuned to an AM broadcast on a car radio and you enter a bridge, tunnel, or parking garage. The AM signal may disappear. If you tun-in an FM signal, it may be strong. The FM wavelength fits through pores in the structure.

In a tunnel, the diameter must be at least 1/2-wavelength not to severely attenuate attempted propagation of a wave through the tunnel.

Best regards, Richard Harrison, KB5WZI

Radio waves of different wavelengths do behave differently.

Long waves of 600 meters or more couple well to the ground and propagate
along it for very long distances. Waves of medium length, from about 100
to 600 or even 1000 meters also couple to the ground but do not travel as
far in that mode. They also reflect of the ionosphere's E and F layers
when those are present, though they are absorbed by the D layer in
daytime.

Shorter waves, from 100 meters on down to about 10 meters often bounce off the F layer for very long distances. These, too can bounce off the E layer. Waves shorter than about 60 meters do not get absorbed so badly by the D layer and thus propagate in daytime. The F layer's contribution depends heavily on energy from the sun. When the sunspot cycle is at a low, like now, propagation on 10 meters is rare (and usually attributable to E layer activity). Generally there is a maximum usable frequency between any two paths. Transmission on a shorter wavelength that that frequency (in other words a higher frequency) will result in the wave simply travelling into outer space.

VHF frequencies normally propagate on line of sight paths, but there are exceptions. Sometimes the E-layer will get a patch that's very hot and the MUF between points about 1200 miles apart will rise up to as much as 250mhz. Sometimes an inversion layer can bend paths back along the surface. And just plain brute force can scatter a signal forward through the shrubbery for quite a distance if you use the right antenna and the right modes (about 300 miles reliably on 144mhz).

Post restructuring License EXAM

(Simplified test approved by all book and magazine publiher and
VE whorehou$e$ who $ay "We need more ham$")

Please PRINT (that means no squiggly lines)

YOUR NAME (what they call you) _____

ADDRESS (where you live) _____

BIRTHDATE (when you were born) _____

EXAM

Instructions: Make a circle (one of these round things O) around the
letter of the best answer! This is so we know what your answer to the
question is!

1. You TALK into a microphone with your _____.

A. Hands
B. Feet
C. Toes
D. Mouth
E. Armpits

2. When you talk into a microphone, you talk into _____.

A. the front
B. the back
C. the top
D. the bottom
E. the wire

3. "HEADPHONES" are worn over the _____.

A. Knees
B. Eyes

C. Toes
D. Ears
E. Lips

4. What do you do with the AC line cord coming out of a power supply?

A. Hold it in the air to pick up signals
B. Pull on it to start the motor
C. Talk into the plug to get real "skip DX"
D. Hook it to your antenna
E. Insert the plug into a source of power

5. A "two meter" radio is:

A. twice as strong as a one-meter radio
B. two one-meter radios in series
C. a CB with two meters on the front panel
D. a good doorstop
E. yo mama

6. A "ten-foot mast" is how long?

A. Ten feet
B. Ten pounds
C. Two meters
D. Tree-top tall
E. yo mama

7. A "Triband antenna" is made to work on how many bands?

A. 1
B. 2
C. 3
D. 4
E. 10

8. The "Marconi" antenna is named after:

A. Marconi
B. Mantovani
C. macaroni
D. Dean Martin
E. yo mama

9. What colors of DIODES can you buy at a Radio Shack store?

A. Red, blue and black
B. Red, yellow and green
C. Orange and brown
D. I am colorblind so this is a discriminatory question and I should automatically get my license because you have been mean to me.
E. I have no intention of ever using DIODES, so I should get my license for free.

10. What color of SLURPEE can you buy at 7-11?

A. Red, blue and black
B. Red, yellow and green
C. Orange and brown
D. I am colorblind so this is a discriminatory question and I should automatically get my license and free slurpees forever because you have been mean to me.

END OF EXAM.

YOUR SIGNATURE (slap yo tag here)

Scoring:

Get THREE correct and you get an EXTRA!!!!
Get TWO right and you get an ADVANCED!!!!
Get ONE right and you get a GENERAL!!!
Miss them all? Just blow the VE and get a no-code Tech Markie!!!

Get a GE SuperRadio III. It's cheap. About $50. It also has a built-in
8-inch ferrite antenna. Cheapest radio I know of that has that big a
ferrite. Also has a screw terminal on back that accepts an external AM
wire antenna. If that doesn't do it, get the Select-A-Tenna external
loop fro

Bill,

Refer to the posters who recommended you search the web. Find a tested
design. There are so-o-o-o many variables.

A few notes from my experience; You can couple to an existing radio four
ways (assuming you don't have a ready-made External Antenna jack):

a) Solder a wire onto the tuning capacitor of the existing radio. This will
detune it, so you'll have to adjust the trimmer. This worked wonderfully
well for a cheap battery portable radio that I used on a Navy ship. It has
decent AM sensitivity without anything connected to the wire, but inside the
ship I needed the connection to use a ship's antenna which was available to
me.

b) Wind a few turns of wire around the AM loopstick, connect one end to a
ground and the other end to your external AM loop.

c) Same as above but wind the turns around the whole radio. You probably
get poorer coupling, but you don't need to open the radio.

d) Put the loop near the radio. (See following anecdote.)

Some years ago, having the same need you describe, I built an AM loop with
a random coil and a junk AM radio tuning cap to resonate it. I just dug it
out. The coil consists of 18 turns of hookup wire around the lid of a paper
case, the box that hold ten reams of printer paper. It only tunes the
bottom third of the BC band, so it's probably got too much inductance. I
can couple to a radio merely by putting it next to the radio; the
improvement is most noticeable on weaker stations and the effectiveness

varies wildly with the orientation of the radio and the loop. If I added an external antenna wire and a ground, things would change.

Acrylic enamel auto paint is good for paiting antennas if you must It is
vertually transparent at RF frequencies.I used to install TVRO systems and
know of a couple of horror stories where the dish was painted with latex
house paint.

Hello Owen, thanks for the comprehensive explanation.

> Which match type did you have problems with?

The 'problem' however was not directly related to lossy lines, but more about why Nec2 would not correctly model the results as achieved by Cebik's spreadsheet. This because both use lossless lines. I can imagine the outcome has a spread around 50 ohms or so, I did not expect results around 20 ohms or even worse.

At the moment I do not have the corresponding models available overhere. I'll post them tomorrow, maybe someone else can figure out what I am doing wrong...

Arie.

> Does anybody know a source for (similar) stub matching software
> (freeware or evaluation), so I can check where things go wrong ?
>
> Thanks in advance,
> Arie.

Arie,

If you are using the 1/4 wavelength series section worksheet, there is a factor of four error. Instead of calculating a 1/4 wavelength line, it calculates a full wavelength. If you will divide each of the values in cells G10 through G12 by 4 you will get the correct line length.

The Beta matching worksheet seems to be correct. I use stub matching on my 20-meter Yagi and the modeled values and my measured values are remarkably close. The stub length given in the worksheet correlates fine with the model.

Regards,

Wes N7WS

CW wasn't all that bad of a filter, but most everyone wants to get rid of
it. After it's gone, I'll just have to stick to the non phone portions of
the HF bands were you still find real hams communicating.

SC

3572. Re: Antenex 900mhz base/repeater antenna NIB

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-08 01:59:07 UTC
From: Dave Schmidt <n9nlu-SPAM-NOT-ALLOWED@nconnect>
Message-ID: <1165543225_1495@sp6iad.superfeed.net>
Source record: 48296
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna,rec.radio.swap

Heh, Antenex ... stay away from Antenex crap. I purchased 3 mobile antennas, a VHF base loaded BB1443 , a UHF center loaded BB4303, a Dual Band CB144/440C about 1-1/2 years ago. I purchased them all on the same day so they all have seen the same amount of use and weather. 4 months after the purchase, the CB144/440C antenna died. The something in the coil failed. While in communications with Antennex (read below) the UHF antenna failed. It seems that you need to locktite the set screws in place due to the tap drill being too big causing a whole lot of slop in the set screw holes.... the set screws rattled out and I lost the whip. Finally, 3 months ago, the VHF antenna finally failed. The plastic housing around the base coil cracked from end to end.

Now keep in mind, I do not remove these antennas, nor do I go whacking them into trees and bridges and stuff.

After I the Dual band antenna failed, I e-mailed Antennex about the problem with a polite message inquiring about if anything can be done to remedy this issue of a dead coil. I received back a very unprofessional e-mail, not even signed from someone from Antenex customer support basically telling me I need to buy a new antenna. I e-mailed the president, VP and a few others within the company - 2 weeks later, someone replys to the e-mail saying sorry for the issue with the customer service person. But no mention to my problem with the CB144/440C antenna. By now the second antenna failed. I e-mailed to the person who e-mailed back to me which was the VP, he never responded back.

Since Antenex supplies the government and the military with antennas, I can just imagine the failure rate with the abuse the military dishes out. Then again, its only our tax dollars being spent on garbage.

Not knocking this base / repeater antenna, MAYBE Antenex puts a little better quality into them ... but definitely Antenex mobile antenas - STAY AWAY FROM THEM, its just a waste of money. Heck, I have an MFJ dual band antenna, been whacked, bent, and abused.... a 10+ year old $20 NMO antenna, and yet its still working.... while the $40 - $50 antennas are all dead.

3573. New Large Wi-Fi Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-08 02:04:12 UTC
From: ab9il_worldwide@yahoo.com
Message-ID: <1165543452.768017.239920@73g2000cwn.googlegroups.com>
Source record: 48297

Hello to all,

Another antenna project for long range 802.11 operation
has been posted to my web page. This one is a long helix,
and performs quite well. A short version, combined with
a satellite dish outperforms the linear focus design
by a wide margin. Give this a try if you're experiencing
weak signals. Today's little Ku band dishes are great for
application in wireless networking and require less set-up
work than the strainers and linear focus reflectors.

Construction details may be found on my web page:

http://www.geocities.com/ab9il_worldwide/wifi3.html

Regards,
Phil AB9IL

I've done a fair bit of googling, and haven't found a decent set of plans to construct a 2m Big Wheel. I have found the original article from 1961, but the resolution in the pdf is lousy.

Anyone have a link?

Hi Tom

I downloaded the 4 pages. Yeah, they are a bit difficult to read, but all
the informationis readable. If there is any particular part that interests
you, I can (hopefully) check to see if it is readable here.

I'll be curious to learn the advantage of this antenna.

Jerry

Made a sketch from Tenth Ed. ARRL antenna book ... gotta love the used bookstore

http://www.n3ox.net/files/bigwheel_sketch.pdf

All red circles go to one side of the feedline, all blue go to the other.

Impedance if the antenna is resonant is apparently about 12 ohms, suggested matching method is to make each element a little bit short so that it's a bit capacitive at the desired center frequency and then use a hairpin inductor to match to 50 ohms.

No details on specific lengths in my book here; just says that each element is "one wavelength" ... If I'm calculating correctly, think that you want to shorten the elements enough that the natural feedpoint impedance of the three paralleled elements is about 12-j21 and then use a hairpin inductor of about +j28 ohms as the shunt across the feedpoint.

Dan

Actually, maybe it doesn't have gain compared to a halo... I'm not really sure... I have an inconclusive 6m Big Wheel EZNEC model with an average gain problem... though at this point it's only showing a -0.5dB average gain or so, and impedance and gain seem constant with segmentation changes, so it's probably not so bad.

I made it back when I was considering building one and modified it a little bit to make the avg. gain work out better.

Anyway, if anyone wants to try to get it to work reliably, there's a model at

http://www.n3ox.net/projects/eznec/6mBigWheel.ez

Hi Dan,
A model I did some years back showed gain very close to a dipole, much
better omni pattern than classic halo/loops and about a dB better gain than
the loops (once you average their gain around the full 360 azimuth).
This from memory.

What average gain did you expect? In case you had in mind that average
gain would be a big positive number, an antenna doesn't create power,
average gain (ie gain averaged over a sphere) MUST be less than 0dB if
it has ANY loss, mustn't it?

Owen

Dan,

I changed your segmentation, W1=1, W8-W43=1, I get average
gain=0.05dB.

Are you sure that W1 should be 15"? That and the spacing of each pair
of conductors out the the ring gaps are going have a large influence
on feedpoint Z. Did you scale this from another frequency?

Owen

Thank You all for your input. I have decided to Build a tuning AM Loop. It doesn't seem like it should too big of a project. It would be nice to have the capability of tuning and I may mess with trying to make it tune some of the lower Shortwave bands as well. Thanks again for all the input. Great bunch of people in here :)
Bill

The way to get gain is to stack them (with phasing) in order to put as much
power as
possible into low angle transmission.

I have 4 stacked 2 meter big wheels originally manufactured by Cushcraft.
Best Regards,
Ed, N5EI

> I may mess with trying to make it tune some of the lower Shortwave bands
> as well.

Easier said than done. If you use a 240uh inductor and you tweaked it for
minimum
interwinding capacitance your high end frequency (might) reach 1700khz. A
switching
system could be used that switched out some of the turns on your inductor,
this could
get you higher frequencies.
If you started with a 100uh inductor and a 365pf cap this would tune about
850khz
to almost 3Mhz.
BTW do you have the formula to calculate the resonate frequency?
Have tried any dimensions and turns and calculated inductors?
Mike

Source record: 48310

I could not find my original data, so I create a new set to try to show
where I have a 'problem'.

Below, a random short inverted-V for 80, delivering a Z-in of around
16.3 - j 826 ohms

```
CM Short Inverted V for 80 Mtr.
CE
GW 1 25 -9.829825 0 14.117083 -0.3 0 21 5e-4
GW 2 3 -0.3 0 21 0.3 0 21 5e-4
GW 3 25 0.3 0 21 9.8298245 0 14.117083 5e-4
GE
LD 5 0 0 0 58000000
GN 2 0 0 0 14 .006
EX 0 2 2 0 1 0
FR 0 1 0 0 3.6
XQ
```

****

Next, the data that was entered in the Cebik spreadsheet, Tab E
http://www.cebik.com/download/ant-match.xls

Using 50 ohm 'coax' (0.66) as feed/match line and 300 open-line (0.8)
as stub.

Yes, a strange combination, but I choose these to get exceptional
results.

```
Antenna Load Resistance RL 16.3 Ohms
Antenna Load Reactance XL -826 Ohms
Frequency in MHz FQ 3.6 MHz
Zo of Matchline ZL 50 Ohms
Velocity Factor of Matchline VFL 0.66
Zo of Main Feedline ZF 50 Ohms
Velocity Factor of Feedline VFF 0.66
Zo of Stub ZS 300 Ohms
Velocity Factor of Stub VFS 0.8

Match-Line Length A 84.56 degrees 12.910 meters <----
Shorted stub length 0.33 degrees 0.061 meters
Open stub length 90.33 degrees 16.716 meters <----

Match-Line Length B 88.51 degrees 13.513 meters
Shorted stub length 179.67 degrees 33.249 meters
Open stub length 89.67 degrees 16.594 meters
```

Electical lengths (ant. to stub) 12.910/0.66 = 19.5606 mtr
(stub itself) 16.716/0.8 = 20.895 mtr

****

Below the Nec-file with Tr-Line lengths as calculated above and a third
50 ohm line from
stub junction to the house.

Delivering a Z-in of 0.93 + j 24.2 ohms ?, If you ask me this should
have been around 50 ohms.

```

Arie,

Your design is for an o/c stub. Haven't you modelled a s/c stub by
connecting the transmission line to W998?

I have checked your proposed design on Winsmith, and it gives a 50
ohms input impedance. Nevertheless, it is hypothetical as it is not
practical to connect a 300 ohm stub to 50 ohm line, 50 ohm line will
be coax (in practical cases) and it is not practical to make a 300 ohm
coax. If you were to mix coax and open wire line, you have a serious
balance issue that you have not dealt with in your model.

The other thing about the design is that two of the transmission line
elements are very close to 90 deg in length, which means that
operation is very sensitive to frequency change.

If you really want to make a 40m inverted v work well on 80m, you
might have to match at the feedpoint. It is hard to get an unloaded

dipole of length 25%wl to work well without matching at the feedpoint.

Just working through a solution using a single o/c stub match using Cebik's calculator for Wireman 551 ladder line, Zo=400, vfr=0.902.

Length of series section is 13.029m, length of stub is 19.163m. This is correct for lossless line.

Now lets look at the Y looking into the series section using the line loss calculator at http://www.vk1od.net/tl/tllc.php , it is 0.030478+j0.067004. Now shunt that with the Y looking into the o/c stub of 0.017872-j0.076378. Add them for a Y of 4.835E-002+j0.143382, or Z of 2.11171146485231-j6.26228362468365 or VSWR of 22:1.

What went wrong?

In some cases, assuming lossless lines is not valid, and you don't really know if you don't calculate the effects of the loss.

Owen

PS: the correct solution will be a slightly shorter series section and a slightly longer stub. It is still not a good (practical) solution.

Hi Dan

I made a model of two Turnstiles (crossed 1/2 wave dipoles) stacked, one above the other. EZNEC shows 2.9 dBi gain at the horizon with free space conditions. The individual dipoles have input impedance of about 68 -J 10.
It seems that two turnstiles, stacked vertically might be a decent choice for a omniazimuth horizontally polarized 2 meter antenna.

I opened the meter of an Hallicrafters SX-117 to mechanically adjust the zero. Once open, the meter appeared to be of the moving iron type, that is with no moving coil. But I was surprised to see that that meter has no spiral torsion springs either; I can only see a metal (?) dish mounted on the axis, part of which lies inside a rather flat coil.

With no spring, I cannot understand what forces the needle to stay at zero scale in absence of current. Therefore I cannot figure out what I should do to adjust the zero.

The HT-44 as well as the EICO 723 use the same type of meter. Dumping is poor, and the needle keeps banging for a while when you apply a DC current.

Richard, at 5am I was just being lazy with quick cut and pastes. Its
all right for you, you have had breakfast and are all fired up!

The important thing is that if you plug the numbers from Cebik's
spreadsheet into NEC (properly terminating the o/c stub), they should
be very close to a perfect match... but even a theoretical model
considering line loss will produce a very different answer. Even more
prospect of departure when practical tolerances are considered as you
note.

Dick,

you read my question too quckly. I was not referring to the electrical adjustment (there is a potentiometer just for that) but to the mechanical adjustment.

In a properly maintained radio, the meter should stay at zero even when the radio is off. That is the reason for the mechanical adustment.

Bill,
Start with AM broadcast and work from there, since that is your primary goal. My smallest loop for AM (2.5 x 3 feet) has a tap for 160, but it doesn't work very well there. These loops seem to work best on AM broadcast and below - not as effective on the higher bands. So, take it in steps, and you will end up with a loop that suits your needs. Plus - they are lots of fun to experiment with. I have downloaded all of Reg Edwards programs (I use RJELOOP3 for loops) just in case his website suddenly goes away. If/when that happens, I will put all of them on my own website so that everyone will still have access to them.

> What average gain did you expect?

Three megaBels ;-) Seriously, though, most antennas I model end up being within 0.05dB of zero. You're right about the spacing, I was making it wide for no particularly good reason ... with the original segmentation and a more realistic spacing of the transmission-line wires (0.6 inches or something), I was getting an average gain in free space with zero wire loss of about -3dB... wider spacing got me closer to zero.

I was changing the wrong things to fix the average gain discrepancy. I'll play around with it more as an educational experience... I posted it mostly because the wire geometry is tricky to get in the first place, lots of creating loops and deleting segments and so forth, but it's easy to modify once you've got it, so I figured it would be of some use.

Now that you've fixed the segmentation, maybe we can put the spacing back and have a working model... I'll have to look into it.

Thanks Owen..

Dan

I used your segmentation and changed the spacing of the transmission
line sections to both 1 inch and 1.5 inches to be more realistic and
played with the transmission line segmentation and can't get better
than -1dB average gain with zero loss in free space.

What should I do

It looks an interesting thing to model.

There are certainly widely ranging claims for its gain in articles on
the 'net.

I have worked up the parameters for a 3D cubic Bezier curve that would
be a good model of half of one of the loops, so I will write some code
to generate a NEC model from it.

Ok, let's try this again.

I googled for plans. Thanks to those that gave me the results I already found, but they were still useless.

One person responded via email, thank you sir.

The others wandered off on related subjects, as this list is want (wont?) to do. That is just fine, I have no problem with that, we learn much that way. I hope we get a decent ez file out of it. And whether it shows the impedance change when stacked that the articles speak of.

Now, does anyone have any plans with things like dimensions? Other than the original 1961 version, which has to have been tweaked at least a little.

Thanks.

One more thing: US Coast Guard ships have what they call a mini-loop HF antenna. It is about four feet in diameter and mounted vertically and that's all I know about it. (I did an electronic systems inspection on a couple of cutters and I know they have the loops for hf xmit.)

I have recently been plagued by rain static on a new vertical antenna,
this a 42 foot vertical fed at the base through an SG230 auto tuner,
and used on all bands. It seems I need a static bleed of some sort, a
choke or resistor. What is the best component to use in an outdoor
environment?
I thought the auto ATU would in itself provide a static bleed path,
but apparently not.

Any thoughts, how have you solved this?

Again Dick, I have adjusted that control many times and any SX-117 owner knows that that contriol exists.

I am instead trying to adjust the mechanical zero which has nothing to do with the control under the rear of the meter housing. Do you appreciate the difference?

Are you sure it's rain static?

Most all verticals have higher noise levels than horizontal antennas. Reason, as it is reported, is that man made noise is vertically polarized.

Take a look at page 4 of the schematic. There is already
a static bleed through 20 turns on a transformer winding
to ground plus about 40K ohms of resistance to ground. You
are already bleeding the static charge, just not fast enough
to get rid of the RF content. The problem is that the
RF content of the precipitation static is finding its
way through your receiver along with the desirable RF
signals. Question is: Is there something that discriminates
against local RF static without discriminating against
desirable RF signals?

Here's my two cents and others certainly do vehemently
disagree with me.

A single precipitation static charge transfer is at a
localized point. Desirable arriving RF waves/photons are
spread out over the entire antenna. That should make them
separable.

Folding the antenna into a loop is one way to reduce
precipitation static. Desirable arriving RF waves are
unaffected by folding as they encounter the entire antenna,
i.e. it's hard to tell the difference between the
performance of a dipole and a folded dipole.

Single charges of precipitation static, however, are
confined to one point on the antenna. If there is a discharge
path to the other side besides through the receiver, the
charge will at least partially take the shortest path of
reduced resistance. IMO, that's why folded antennas are
quieter than open-ended antennas as far as precipitation
static is concerned.

The way I reduced the problem with open-ended antennas is
to use heavily insulated wire. Bare conductors transfer
all charges. 600 volt insulation blocks charge transfer. In
my experience, 1000v insulation blocks most charge transfer.
I use something called "Quietflex" that has 1000v insulation.
Most of the precipitation static doesn't transfer to

the antenna wire while RF waves/photons flow right through the insulation with little attenuation. I suspect plastic encased antennas are quieter than bare antennas.

There is a wealth of information on precipitation static on the web, a lot of it having to do with antennas on airplanes. Folding and insulating are two ways they have solved the problem.

Folding or insulating your vertical may or may not be feasible. If you solve your problem, please share it with us here.

I had already checked the index in my oldest ARRL Antenna Book, circa
1974, and nothing in there. Argh.

I sure wish I had a copy of the 1972 VHF Manual. Our Northern Lights RC
monthly breakfast is in about an hour, I'll check there and see if
anyone has that manual. It's a good bet since W0AUS, the blazing core
of our 10 GHz SSB/CW group, has probably been a ham for over 60 years.

Thanks for the tip.

Interesting Cecil, my vertical antenna is constucted from a 42 foot length of coaxial cable using the outer braid as the radiator (but the inner and outer are shorted together anyway) and this fat vertical "wire" is suspended inside a telescopic fibre glass pole from Spiderbeam (not the conductive type). So, I guess my verical wire is quite well insulated and certainly not in contact with charged rain. We've had particularly heavy rainstorms lately in France and this is definitely rain or rain induced static., starting and stopping in sympathy with the rain storms very easy to identify.

Dave:

Frankly, I think that the statement, "most man made noise is vertical polarized" is a myth. How many power lines do you see running vertically? How many extension cords do you see running vertically? How many phone lines do you see running vertically? Etc, etc.

I think this needs looked at in a new light. Now most 160m antennas are easier to construct for horizontal operation--perhaps this is where the myth got started?

Is anything about your antenna in contact with charged
rain? Your noise problem might have the same cause
as lightning, i.e. the global atmospheric electrical
circuit. You might be experiencing simple corona
discharge.

Cecil:

I am slow to fence with you, your logic is impressive; however, perhaps this "safe guard" has failed? It is hard for me to picture static which is able to resist (pun intended) a path to ground ...

I understand. I don't have have a problem with that aspect of the organization, and since it involved my children, I'd prefer to keep it the way it is. Adults can do what they want.

> given the way my
> private has been invaded and praded by Steve and his freind I suspect
> I need not explain why we disagree about the BSA

But is has nothing to do with the BSA. Robesin is not in the BSA and I wouldn't want him around my children or anyone else's. But he probably has lots of contact with Cadets; hopefully they're using at least the rule of two.

Hi Tony,

It is a fair comparison using a well known modeler. They cite EZNEC
which is our "gold standard" here for modeling. True, this is an
amateur group, but there are a lot of professionals here, many with
military experience, obtained directly or through contracts. None
would shy from recommending EZNEC for professional work.

Performance-wise the two are a wash. One dB accuracy is exceedingly
difficult to achieve in the field, and all the variables of
installation, terrain, use, what-have-you could easily erase slim
advantages. Of all things to be considered is height and visibility
and even here, both seem to be equivalent. Matching is examined and
taken care of suitably for each's design - again equivalent.

The only difference appears to be that the OE-254 appears to suffer
some loss. How and where, the authors don't seem to be either aware
of it, or go into any explanation. Still, even with this the OE-254
seems to be a performer.

Choose the one with the fewest parts (or simplest design).

Hi all,

I have two omni dipoles @ 2.4Ghz, one positioned for vertical polarization and the other horizontal. I have stiff coax feeding these two antennas. The horizontal antenna is above the vertical, and the coax feeding the horizontal runs pararellel with the vertical antenna around 2 wavelenghts (24cm) away. My question is will the signal on the coax leak onto the vertical antenna? I want the two to be as orthogonal as possible. I'm not really sure on the physics involved but is there a standard seperation that is required to minimize this effect or will they always be coupled if I run the lines in this manner? Thanks for any info,

Kev

I have read the GIs like the smaller size of the COM-201B and often set
them up directly on the ground without a mast. The OE-254 has had some
problems with the center hub breaking when stressed and there are more
parts to it. The 254 cannot be used without a mast.
Bob

If the SG-230 weren't there you would be right. But
the SG-230 already has two built-in paths to ground
from the main RF line. One is about 40K ohms resistive
and the other is 20 turns on a transformer, probably
a toroid. Your high-resistance path would probably
have negligible effect in this particular situation.

Tom, W8JI, explained it as not just a static charge
problem but as an RF problem. If the impedance is
low enough to discharge RF static, then it is also
low enough to discharge desirable RF signals. What
a parallel impedance does is prevent arcing due to
static DC buildup but it does little to prevent RF
noise due to precipitation static which is many small
discharges but only one small one at a time. (Someone
reported being able to count the charged snowflakes.)

In the absence of a parallel impedance as exists in
the SG-230, a parallel impedance can certainly eliminate
DC arcing along with its associated corona so it's not a
bad idea. But precipitation static is a number of small
hits each generating a small amount of RF energy. The
only way I know of to reduce the amount of that RF energy
reaching the receiver is to partially short it out with
a loop antenna or insulate the antenna from the physical
hits. And in fact, those are the most popular ways of
reducing precipitation static on airplane antennas.

A small percentage of the length of wires - a very large
percentage of the vertically polarized noise. Probably two
S-units of noise at my QTH that goes away during a power
failure.

Cecil:

Stated was:

"Interesting Cecil, my vertical antenna is constucted from a 42 foot length of coaxial cable using the outer braid as the radiator (but the inner and outer are shorted together anyway) and this fat vertical "wire" is suspended inside a telescopic fibre glass pole from Spiderbeam (not the conductive type). So, I guess my verical wire is quite well insulated and certainly not in contact with charged rain."

How better could the actual metal radiator (receiving element) be insulated from the physical striking of rain drops, other than in the nonconductive fiberglass casing it already resides in? What am I missing?

Warmest regards,
JS

Whoa there, Art. There seems to be confusion between
two topics. As far as I know, there is no obvious
difference between the precipitation static levels
on a horizontal Vs vertical antenna. That this
particular antenna is vertical is mostly irrelevant
to the alleged precipitation static problem. It could
just as easily be happening with a horizontal antenna.

The fact that the noise might be attributed to something
other than precipitation static might involve vertical
polarization but I don't think precipitation static has
much to do with polarization. A wind-driven charged
particle is just as likely to encounter a vertical wire
as a horizontal wire.

Cecil:

Undoubtably, in a power failure, "most all" of the noise, both horiz and vert, goes away. How to you differentiate between what is the horiz component and that of the vert component?

>polarized" is a myth. How many power lines do you see running

Perhaps the explanation for the observation that the vertically
polarised component of man made noise is greater at a receiver antenna
than the horizontal component lies in the propagation mechanism.

Most man made noise is received from nearby and by ground wave, and
vertically polarised ground waves are attenuated less than
horizontally polarised waves over the same path.

This explanation is supported by the observation that the closer one
is to a high intensity man made noise source (but still within
radiating far field), the less variation in field strength with
antenna polarisation.

Owen

Netnews is a challenge. Apparently you have read his
followup posting without reading mine. Just be patient.
My followups will arrive on your server sooner or later.
For instance, if he has uninsulated elevated radials,
the same thing might be happening. Or maybe it's noise
from lightning and not precipitation static at all.

There are two articles at http://6mt.com/2tech.htm and the one I saw
with my Windows fax viewer has dimensions in inches, and the type can
be blown up pretty big with the viewer. ??

Gee, maybe you should save your money and buy your OWN home,
then you can do what you want with it.
An even better experience would be, buy a home with your own money
and rent it to those that think "Landlords suck assholes"
After a few missed rent payments your outlook will suddenly change, you
will
wonder why does that %^&$#^$ think I should support him. It's not my fault
he lost
a job, got fired, car broke down, had to take the kid to the emergency room.
It's not my fault he didn't save any money for a rainy day!
My most fun story is the guy that replaced a mailbox, he was in the middle
of
being kicked out. He went out and bought a $40 mailbox expecting me to pay
for it.
I told him to keep the mailbox. When he left he took the mailbox. The post
for this
mailbox was a buried telephone pole, it wasn't going anywhere.
When I installed my new $5.00 mailbox I mounted a 2"x6" board to the pole
with
5" x 5/16" lag bolts, then I mounted the mailbox to the 2x6 with seven 3
1/4" drywall
screws.
I would have liked to seen his face when he whacked that mailbox and it
didn't go
flying away. I hope he didn't hurt himself, NOT
He was gone about three days before he did this. I waited another week and
put up a new mailbox.
Mike
PS. One day the toilet overflowed I had to remove about 40 kotex from the
sewer

pipe one cold day in January.

PSS. sold all the rentals no more %^&$#^$ to put up with.

> component and that of the vert component?

I continue to operate on backup power during an AC
power failure. The change in noise level on my
horizontal dipole is not very noticeable. The change
in noise level on my vertical is 2+ S-units. It is
obvious that the 60 Hz power lines furnish the source
of the vertical noise with power. I am still not sure
of the source of the vertical noise but I strongly
suspect the ground wire on the pole in my front yard
that contains a power factor capacitor. If I bring
my portable AM radio close to that ground wire, I
cannot even hear the local AM radio station.

>Do you appreciate the difference?

Hi Tony,

Nope.

The meter is always in a condition where current is flowing given that it shares the cathode load. Paragraph 5-5 says quite clearly how to set zero for a zero signal condition. Basically, the design reveals an admission that there is no "zero" in the first place (merely a minimum).

Aside from that, there is no need to be concerned about a meter reading for a receiver that is turned off. In short, any attempt to force a mechanical zero would be negated by the "electrical zero" set and S-9 calibration.

It seems to me that static electicity, and
hence noise, can be induced through the fibreglass. I used
to have horrible wind static on a dipole made with insulated wire.
I would suggest that the rain striking the insulated material could
also induce a static charge.

Hi Kev

I notice that you arent getting an answer from the guys on this News Group
who actually know how to properly solve the problems you are concerned with.
Are you concerned about inducing RF into one coax because of its being 2
wavelengths away from a radiator parallel to it? If so, I can assure you
that the isolation from the vertical antenna to the inside of the paralled
coax will be Very high. I'd expect *that* kind of coupling to be so low
that it would be difficult to evaluate it.

The antennas will be "orthoganal" because they are physically mounted that
way.

Jerry

Cecil:

Yep. EXACTLY, the same problem here.

I constructed a wideband fsm with a fet front end amping up the rf, then through a full wave rect and feeding two opamps in a lm324 acting as a VERY high gain dc amp, plug for ferite/"rubber duck"/telescope antennas. This finds the groundwire on a pole adjacent to my yard is a culprit, when brought close it pegs the meter and turns on the led (powered by extra opamps on board the lm324 acting as a comparator and voltage follower) in the output circuit.

There is also a large, square, distribution xfmr where there are underground lines, although it appears perfectly shielded, it is yet another culprit on the opposite side of my property and gives a substantial reading on the same meter.

Numerous complaints from me has had the power company send out individuals with an am radio, as you describe, they are quite taken with my "noise meter" when I show it to them, and the audio on their am radio confirms my meters reading--however, the noise is still there ...

I am happy they like my meter! <straight face>

Warmest regards,
JS

Cecil
I am just putting up something for thought

Apparently stacked antennas of the horizontal style can avoid a lot of
static noise
if they disconect the upper array. Could this possibly mean that the
horizontal array will not pick up a vertically phased noise in the near
region. I know nothing in this area but just offering something that
could be discussed.

That this

he OP mentioned that the static comes and goes with approaching and receeding rain fronts... Likely he has a significant component of coronal discharge... He may PERHAPS reduce the induced noise a bit with ball on the top of the vertical, a copper float from the toilet works well, or even a nice capacity hat... NOw this is a topic that has been roundly beaten within an inch of it's life on other forums, but perhasps we are bored enough here to go all through it again <groan>

> and S-9 calibration.

Yes, I agree that is in principle there is no need to be concerned about a meter reading for a receiver that is turned off. But I am instead concerned about that, because I like to have all my equipment in perfect order, and a meter that does not stay on its zero when the radio is turned off is something that I dislike and anyway wish to fix.

If I would not have had such requirement, I would not have put the question because it is fairly evident that, when the radio is on, the zero can be adjusted by means of the control indicated in the manual. All old receivers have a zero control for the S-meter.

Moreover, the same problem anyway occurs for the RF output meter of the matching transmitter (Hallicrafters HT44), which is of the same type. But in the HT44 there is no electrical zero adjustment control, so the only way of zeroing the meter is to open it and adjusting it mechanically.

By the way, in the meantime I have found the way of zeroing the meter, so it is no longer an issue.

This is increasingly becoming a pipe dream, as more and more neighborhoods put together ******* CCA's or whatever they call them this week, and dictate what color paint you can have on your home, what sort of topiary, and countless other minutia. Covenant communities should be outlawed. Whatever happened to a man's home being his castle (i.e. personal property rights)?

This topic tends to be provocative. You have heard/read everyone's opinions/measurements in the past.

What is interesting in F5VJC's account is that the vertical is surrounded by what may be a good insulator. Additional information that will be of interest includes:
1. What is in the vicinity of the antenna? How far from exposed conductors, house, barn, trees, and such. Are objects within ten wavelengths higher than the antenna?
2. Are guy wires used to support the antenna?

Some contend that P-noise exists and some contend that it does not exist associated with fixed antennas. F5VJC might be able to add a data point.

John, at 60 Hz a horizontal wire carrying current has a very strong magnetic field. The 'right hand rule' indicates the magnetic field, a near field effect, is vertically polarized.

My 60 meter horizontal is quiet. My 60 meter vertical, about 30 feet from the horizontal, has a good S4 noise level on the same radio at the same time.

out here in the great hinterland... more than an hour drive from any of the
great 'blue' cities. you can still find land that is wild and free, where
neighbors help you put up towers instead of putting them down, and the big
question at a zoning bylaw hearing is if the new bylaw is meant to stop
celular companies from coming into town... the question was asked because
the person didn't want the bylaw to slow them down, because they couldn't
get service now and wanted it!

No, the landlord would still invest the money he earned, paid taxes on,
paid taxes again in the form of, sales tax, gasoline tax, property tax,
telephone tax, cable tv tax, then managed to (chose to) save.
He would just chose a different investment vehicle. Don't fret
he wouldn't need a box to live in. The landlord would still be a saver,
an investor and not live paycheck to paycheck.

3674. 30 helpful hints to help new and No-code hams. Monthly post.

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-10 00:52:53 UTC
From: Slow Code <my.mail@no.spam>
Message-ID: <FTIeh.8313$sf5.5152@newsread4.news.pas.earthlink.net>
Source record: 48248
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.policy

The 30 Steps below will help all No-Code Hams, it will also help you to find others just like yourself. These 30 steps should also be added to the present writtens.

Step One: Use as many "Q" signals as possible. Yes, I know they were invented solely for CW and are totally inappropriate for two meter FM, but they are fun and entertaining. They keep people guessing as to what you really meant. I.E. "I'm going to QSY to the phone." Can you really change frequencies to the phone? QSL used to mean, "I am acknowledging receipt", but now it appears to mean, "yes" or "OK". I guess I missed it when the ARRL changed the meaning. It is also best to use "OK" and "QSL" together. Redundancy is the better part of Lid-dom.

Step Two: Never laugh when you can say "HI HI". No one will ever know you aren't a long time CW rag-chewer if you don't tell them. They'll think you've been on since the days of Marconi.

Step Three: Utilize an alternative vocabulary. Use words like "destinated" and "negatory". It's OK to make up your own words here. I.E. "Yeah Tom, I "pheelbart zaphonix" occasionally myself."

Step Four: Always say "XX4XXX" (Insert your own call) "for I.D." As mentioned in Step One, anything that creates redundancy is always encouraged. That's why we have the Department of Redundancy Department. (Please note that you can follow your call with "for identification purposes" instead of "for I.D." While taking longer to say, it is worth more "LID points".

Step Five: The better the copy on two meter FM, the more you should use phonetics. Names should be especially used if they are short or common ones. I.E. "My name is Al... Alpha Lima" or "Jack.. Juliet Alpha Charlie Kilo." If at all possible use the less common HF phonetics "A4SM... America, Number Four, Sugar Mexico." And for maximum "LID points", make up unintelligible phonetics. "My name is Bob... Billibong Oregano Bumperpool."

Step Six: Always give the calls of yourself and everyone who is (or has been) in the group, whether they are still there or not. While this has been unnecessary for years, it is still a great memory test. You may also use "and the group" if you are an "old timer" or just have a bad memory. Extra points for saying everyone's call and then clearing in a silly way "K2PKK, Chow, Chow."

Step Seven: Whenever possible, use the wrong terminology. It keeps people guessing. Use "modulation" when you mean "deviation", and vice-versa.

Step Eight: If someone asks for a break, always finish your turn, taking as long as possible before turning it over. Whenever possible, pass it around a few times first. This will discourage the breaker, and if it is an emergency, encourage him to switch to another repeater and not bother you.

Step Nine: Always ask involved questions of the person who is trying to sign out. Never let him get by with just a "yes" or "no" answer. Make it a question that will take him a long time to answer.

Step Ten: The less you know on a subject, the more you should speculate about it in the roundtable. Also the amount of time you spend on the subject should be inversely proportionate to your knowledge of the subject even though you have no damn clue.

Step Eleven: Always make sure you try to communicate with only a handheld and a rubber duck antenna. Also, make sure you work through a repeater that you can hear very well, but it cannot hear you. This will put out a kind of "LID mating call": "Well, Joe, I can hear the repeater just fine here. I wonder why it can't hear me?" You will score maximum LID points if you are mobile, and with the radio lying in the passenger seat.

Step Twelve: If you hear two amateurs start a conversation, wait until they are twenty seconds into their contact, and then break in to make a call, or better yet to use the auto-patch. Make sure you keep the repeater tied up for at least three minutes. This way, once the two have re-established contact, they won't even remember what they were talking about.

Step Thirteen: You hear someone on the repeater giving directions to a visiting amateur. Even if the directions are good, make sure you break in with your own "alternate route but better way to get there" version. This is most effective with several other "would-be LIDs", each giving a different route. By the time the visiting amateur unscrambles all the street names whizzing by in his mind, he should have moved out of the range of the repeater. This keeps you from having to stick around to help the guy get back out of town, later.

Step Fourteen: If an annoying station is bothering you, make sure your other "LID" buddies have a "coded" frequency list. Even though "CODES" are strictly forbidden on Amateur Radio, it's really neat to practice "James Bond" tactics.

Step Fifteen: Always use the National Calling Frequency for general conversations. The more uninteresting, the longer you should use it. Extra points are awarded if you have recently move from an adjacent frequency for no reason. Make sure when DX is "rolling" in on 52.525 that you hang out there and talk to your friends five miles down the road about the good old CB days!

Step Sixteen: Make sure that if you have a personal problem with someone, you should voice your opinion in a public forum, especially a net. Make sure you give their name, call, and any other identifying remarks. For maximum points, make sure the person in question is not on the repeater,

or not available.

Step Seventeen: Make sure you say the first few words of each transmission twice, especially if it is the same thing each time. Like "roger, roger" or "fine business, fine business". I cannot stress enough about encouraging redundancy.

Step Eighteen: If you hear a conversation on a local repeater, break in and ask how each station is receiving you. Of course they will only see the signal of the repeater you are using, but it's that magic moment when you can find a fellow "LID", and get the report. Extra points are awarded if you are using a base station, and the repeater is less than twenty-five air miles from you.

Step Nineteen: Use the repeater for an hour or two at a time, preventing others from using it. Better yet, do it on a daily basis. Your quest is to make people so sick of hearing your voice every time they turn on their radio, they'll move to another frequency. This way you'll lighten the load on the repeater, leaving even more time for you to talk on it.

Step Twenty: See just how much flutter you can generate by operating at handheld power levels too far away from the repeater. Engage people in conversations when you know they wont be able to copy half of what your saying. Even when they say your uncopyable, continue to string them along by making further transmissions. See just how frustrated you can make the other amateur before he finally signs off in disgust.

Step Twenty One: Use lots of radio jargon. After all, it makes you feel important using words ordinary people don't say. Who cares if it makes you sound like you just fell off Channel 19 on the citizen's Band? Use phrases such as "Roger on that", "10-4", "I'm on the side", "Your making the trip" and "Negatory on that".

Step Twenty Two: Use excessive microphone gain. See just how loud you can make your audio. Make sure the audio gain is so high that other amateurs can hear any bugs crawling on your floor. If mobile, make sure the wind noise is loud enough that others have to strain to pick your words out from all the racket.

Step Twenty Three: Start every transmission with the word "Roger" or "QSL". Sure, you don't need to acknowledge that you received the other transmission in full. After all, you would simply ask for a repeat if you missed something. But consider it your gift to the other amateur to give him solace every few seconds that his transmissions are being received.

Step Twenty Four: When looking for a contact on a repeater, always say your "listening" or "monitoring" multiple times. I've always found that at least a half dozen times or so is good. Repeating your multiple "listening" ID's every 10 to 15 seconds is even better. Those people who didn't want to talk to you will eventually call you, hoping you'll go away after you have finally made a contact.

Step Twenty Five: Always use a repeater, even if you can work the other station easily on simplex ... especially if you can make the contact on simplex. The coverage of the repeater you use should be inversely proportional to your distance from the other station.

Step Twenty Six: When on repeaters using courtesy tones, you should always say "over". Courtesy tones are designed to let everyone know when you have unkeyed but don't let that stop you. Say "over", "back to you" or "go ahead". It serves no useful purpose but don't worry, it's still fun!

Step Twenty Seven: Use the repeater's autopatch for frivolous routine calls... especially during morning or evening commute times. While pulling into the neighborhood, call home to let them know you'll be there in two minutes.... or, call your spouse to complain about the bad day you had at work. After all, the club has "measured rate" service on their phone line so they get charged for each autopatch call. Your endeavor is to make so many patches in a year that you cost the club at least $20 in phone bills. That way you'll feel you got your money's worth for your dues!

Step Twenty Eight: Never say "My name is ....." It makes you sound human. If at all possible, use one of the following phrases: a) "The personal here is ..." b) "The handle here is..."

Step Twenty Nine: Use "73" and "88" incorrectly. Both are already considered plural, but add a "s" to the end anyway. Say "73's" or "88's". Who cares if it means "best regards" and "love and kisses." Better yet, say "seventy thirds"! (By the way, seventy thirds equals about 23.3).

Step Thirty: If the repeater is off the air for service, complain about the fact that it was off the air as soon as it's turned back on. Act as though your entire day has been ruined because the repeater wasn't available when you wanted to use it. Even thought you have never paid a penny to help out with the upkeep of it.

My landlord was a no-code ham and he didn't want me to have an antenna because he didn't want me to have fun making CW contacts, so I slapped the shit out of him and now I have a 5 element tri-bander up 100 feet and I made him pay for it. I told him I'm not paying anymore rent until he learns CW, so I got him learning code now too.

The heated part of the discussion was because of
the assertion that precipitation static does not
exist. One only need do a web search for "precipitation
static" to see that it is an accepted, well known, well
defined physical phenomenon.

Don't know about his static problems but it seems
to me that it doesn't make much difference whether
the antenna is moving or the charged particle stream
is moving. It's all relative. :-)

Yes, but zip the files them or they won't get here.

Also send me a regular email with no attachments, and I'll give you an
alternate address in case the system eats the zip, too.

That went away with all the other rights such as the right to use a telephone without fear of the government listening in (without a court order) and losing your pilot license if a neighbor gets pissed at you for something and calls homeland security and says you're a threat (no due process in that case, they just automatically yank it I'm told). Very sad to see such abuse of power. I think everyone should vote every elected official out at the next opportunity. Let's start with a clean slate and make the lousy reps get regular jobs like the rest of us.

I know I am. What's that got to do with my opinion that I stated?
And people like you (I assume you say I'm full of shit for wanting to
vote out deadbeats) keep voting the useless crumbs back into office,
year after year. I will clarify a bit though...yes you still have a
right to own your own home. You just might not be able to use it for
what you want (does Michigan require land use permits?) If I want to
put a private use runway on my property I have to get a permit and the
county sends letters to all adjoining property owners to see if there
are objections. To me, my airplane is a recreational vehicle. Why
doesn't the county send me a letter to see if I object to neighbors
using THEIR recreational vehicles (snowmobiles, ATV, etc.) running them
up and down behind my house at 2AM when the bars let out?

I havea 3 piece galvanized unit consisting of 20 ft. tall crank actuated pivoting tower section, 20 ft. tall center crank-up pole and pivot post. Unit goes from 40 ft. vertical to 5 ft parallel to the ground in 15 mins. This unit is complete and ready to use - just add antenna. Local delivery available. Tampa/St.Pete to Venice, FL $350.00 OBO Pics avail.

"They that give up essential liberty to obtain a little temporary
safety deserve neither liberty nor safety." Benjamin Franklin

Government is not reason. Government is not eloquence. It is force. And,
like fire, it is a dangerous servant and a fearful master.

-George Washington

"You have rights antecedent to all earthly governments; rights that cannot
be repealed or restrained by human laws; rights derived from the Great
Legislator of the Universe."

-John Adams.

Need I say more ?

Thanks Ace...

I guess one of my buttons got pushed...I just think it's such a shame
that people in general (and I'm guilty of it too) just look the other
way at "bad government" and let elected officials get away with the
stuff they do. I mean, how many of us would get to break laws at work
and not get fired? MAYBE government would get better if elected
officials actually feared voters? 2 cents worth...

So, I want to make a loop antenna for AM, and I'd like to ask a question that I guess must have been asked time and time again: Does the material used to make the wire (copper, steel, aluminum) affect the inductance of the loop?

3699. Re: Material of wire: does it affect a loop antenna's performance?

It affects the Q more than the inductance. Stainless
steel 75m mobile loading coils have been measured
to be 4+ dB down from a copper coil. If you want
a really efficient AM loop, use a super-conductor. :-)

Yup - as long as those consumers know what they are getting into.

In more than a few places, the buyer doesn't know a house has covenants unless they ask exactly the right questions and insist on the answers in writing. Many folks live in houses with very restrictive covenants without ever realizing it, because they don't do anything that violates the covenants.

One of the ironies of all this is that covenanted properties tend to appreciate in value more slowly than unrestricted ones. This makes them less expensive - and more popular with buyers.

Hello Deni:

I have had such problems with rain noise. A ground plane antenna mounted to the side of the house had severe rain static noise.

After checking the antenna and coax it was found that a new roof was installed and sheet metal pieces where installed on the roof before the roof paper and roof was installed. After finding this out, the mast was moved away and insulated from the side of the house.

This reduced the rain static in the receiver significantly. What I think was happening was the heavy rain static energy was using the mast as a ground rod, inducing the noise into the antenna.

I have at times experienced severe rain static, but only two times when the the rain was a complete heavy down poor of rain, that only lasted a few minuets. I think its possible that some, but not all weather brings the rain static and most antenna installations will hear it.

Jay in the Mojave

When I bought my present house, the real estate agent
had no idea about any restrictions concerning this
property. After a lot of digging they were uncovered.

Others have reported experiencing severe snow static.
My worst precipitation static problems occurred in
the Arizona desert on a dry sunny day with 40 mph
winds filled with charged dust particles streaming
across the desert. It actually caused a burst of
arcing at my coax connector.

Number of things are getting confused and lumped.
There are different types of "Rain Static" and "noise"

1. One that W5DXP experienced in dry winds of Arizona, is charging of metal parts by air mass movement and generated charge by it. Either in immediate vicinity of the antennas or higher up. Insulated wires, loops and balanced antennas and feeders help here.

2. High altitude static buildup during the storms. Is due to buildup of static in higher altitudes, accompanied by lightning discharges. Here the umbrella effect of having higher structure with "capacitance hat" like Yagi helps to drain the charge from the vicinity and static free reception from lower antennas is possible. Stacked beams are example, where lower antenna is dead quiet while top one gets S9+20 frying noise. Insulation or no insulation immaterial here.

3. Discharge from the rain droplets on the antenna elements is like #2. Insulated elements help here to a point.

Power line noise. If the source is a bad connection in power lines system (point source) that noise is "everything polarized". Depends how the antenna and structures around it participate in the radiation from it. Argument that it is vertically polarized has more to do with RX antennas and their pattern rather than "pure" polarization. Verticals have major lobe at the horizon and they "see" everything near by. Horizontals at typical height have major lobe at some higher angle, mostly "looking" up and have a null at the horizon, "ignoring" nearby sources of noise. Then there is the propagation mode effect contributing to the noise propagation and affect on receiving systems.

Regardless of W8JI claims that small loop antennas don't have electrostatic shield - effect, they can be of great help in discriminating against the near by noise sources by using electrostatic shields. And yes Virginia, in the close proximity there is a separation of E and H fields.

One has to be careful and properly identify the type of noise, ways of propagating and means of suppressing it. The best way is to do it at the antennas. For example I had horrible noise situation from HV power lines. The most effective way was to null it out by mutual positioning of the main antenna (Razors) and 3 el. Yagi between them. I could suppress, null out noise of 30dB over S9 down to almost nothing. Then the noise blankers and filtering are put to work.

Hopefully not literally!

The real kicker in all of this is the buyer who doesn't know the right
questions to ask,
and how to evaluate the answers. A verbal statement by the agent, owner
or anybody
else is worthless when confronted by legally recorded covenants in
black-and-white.

These questions have to be asked up-front - preferably before even
looking at a
property.

Always remember that RE agents don't make any money until a sale
closes.

Generally neighborhoods don't put them together. Homeowners
associations and the related CCR's found in the deed are usually
required by either city or county planning commissions as a tradeoff
for denser than normal housing in planned communities. With those
restrictions you usually get community open space and some level of
community recreation facilities, etc.

Whether they are good or bad or something in-between really depends on
what you want in your locality. Some of us enjoy the freedom to do
more-or-less what ever we want with our house. Along with that right
comes the responsibility to acccept whatever your next-door-neighbor
does with his house. About 10 miles away is a community with out a
HOA that is composed of 80 year old well maintained brick or wood
colonial houses. One guy has painted his brick home contrasting colors
of purple, pink and blue. Another puts fills up most of his yard with
at least 100 beatup plastic santas and other xmas paraphernalia. And
yet a third house has a very large oak that was chainsaw sculpted to
look like a 30 foot nude with huge breasts and 2 large branches made
into arms extended open toward the house. And these are neighborhoods

with houses that sell for $900,000 and up.

I would prefer to not have stuff like that next door and am willing to trade off the right to paint my mailbox any color.

> Covenant communities should be outlawed.

Why should they be outlawed? If you don't like them just move to a location where there isn't a home owners association.

> Whatever
> happened to a man's home being his castle (i.e. personal property rights)?

What specifically are personal property rights. I have yet to find the locality where you can do anything you want on your property.

The member of our team that is finishing the final draft of the Request for Discussion (RFD) agreed to a firm deadline of January 1, 2007. The team has reviewed, and agreed to, prior working drafts of the RFD, as well as submission guidelines for the proposed new newsgroup, so this is just cleanup and tweaking at this point. The submission guidelines were recently posted to misc.test.moderated. We will have an RFD to pass along to the news.announce.newsgroups moderator to crosspost to this newsgroup shortly after January 1st. Moving the discussion period to after Christmas is also desirable in order to have a bigger audience for the RFD, and give everyone ample opportunity to provide feedback free of holiday distractions and time demands.

In the meantime, we've been testing the robomoderation software, Secure Team-Based Usenet Moderation Program (STUMP). Several rec.radio.amateur.policy participants have graciously agreed to send us test submissions, many of which we have approved and posted to misc.test.moderated. At this point, anyone reading this newsgroup is welcome to send us test postings. Send such submissions to:

rec-radio-amateur-moderated@panix.com

We'll process them as if they were actual submissions to the proposed moderated newsgroup. Anything we approve will be posted to misc.test.moderated, so please don't send anything to that address that you don't want posted to Usenet, or at least add the text "not for publication" or "do not approve." We would be particularly interested in test postings that are PGP signed.

Watch this space for further information after the first of the year.

A lot of meters dont "zero" on purpose. This area of the meter is inherently
inaccurate so they are biased off of this point either electrically,
mechanicanically or even magnetically on purpose. Forcing these meters to do
otherwise isnt always making them"right". Unless there is some indication
that there is an inaccuracy with the meter and zeroing will help it is best
left alone. For example I have a linear scale capcitance meter that must
be"zeroed" at about 2pf for it to be accurate on the rest of the scale.
Perhaps one day I will solve this problem by replacing the 50uA meter
movement with a digital meter but it has served me well for 30 years so I
think I will leave it "as is" for now. I guess I could make it "zero" on
power off by applying a bias voltage to the meter when it is on to slightly
move the meter off the peg but attempts to do this have shown that it would
significantly complicate the circuitry and comprimise accuracy.

The only rain static I have observed is during a sudden downpour. This is on
a longwire antenna. If the rain last more than a few minutes the static goes
away. I have wondered sometimes if this isnt caused by the rain hitting a
dry antenna. No real reason to assume this is fact but it does seem to fit

the observation. Perhaps I will run out one day and hose the antenna down and see if this stops the static. |:).

This seems to be even more the case when I take my radio down to florida from north carolina. In florida we have afternnon storms that you can almost set your watch by. When they hit the haose I usally get a steady build up of noise then suddenly it dies down. It seems to die down durung the heaviest part of the rain.

Finally got to work on the antenna this weekend. My daughter sweated a couple of the copper joints. I think she sees this a sculpture. Also she got to hear some of the birds as they went overhead on the scanner. This was a big kick knowing she was hearing signals from space. Nice to know she isnt so jaded she cant appreciate something like this.

I don't know Bill.

The condescending operator of a SPST switch is still here.
Hopefully he will operate his appliance like transmitter of 3 million
less transistors than the one he is sitting in front of and pound some
brass.

On topic, I hope to but up my Windom soon. Built an air core 4:1 balun
by wrapping 14 bifilar turns around a 1.24" PVC pipe. Testing with a
200-ohm dummy load, the balun seemed to work fine 20 meters und up, but
performed poorly at lower frequencies. I inserted two pieces of ferrite
rod and it now operates nicely down into 160 meters but not so well at 10.

Because the balun is working well on the intended bands, I potted it up
with epoxy and will hang the antenna soon. But it is frustrating that
the antenna will not probably do well on 10 meters.

Regards,

Chris KC8FRJ

Anyone who says you can't revive a dead horse with a good, firm beating has not met this group :)

I suspect that there are several points of agreement with the majority of the group, however not everyone will agree, heck I may choose to disagree with something right after I write it......

That dry wind will cause high voltage charging -and arcing- of insulated antennas and static noise, especially on long wires - that this is mostly friction charging, a similar mechanism to rubbing silk on glass, though charged body impact of dust may be relevant...
That dry, falling/blowing snow causes extreme levels of static noise on insulated antennas - by mixed phenomenon of friction static and charged body impact...
That static noise builds up as a rain front approaches, with or without associated wind... That this static noise is separate from lighting discharge impulses....
That lightning discharges cause noise - inductive noise...
That rain causes static noise on insulated antennas - charged body impact primarily, I don't know about friction charge...
That heavy rain 'may' lessen associated static noise....
< I haven't personally experienced this - is it the magnitude of the rainfall or the fact that the highly charged front has passed on by and the falling drops are now less charged?>
That a grounded tower with an antenna stack can have the top antenna experience heavy static noise while lower antennas will have significantly less static roar...
<my opinion is that coronal discharge from the top antenna elements is inducing noise into the top antenna circuit, and that the coronal flow that would have occurred off the lower antenna elements is suppressed and drained to the top antenna by the differential voltage on the higher antenna>

So, in the end it may be that the charging of the antenna circuit by either friction or charged body impact causes less noise than the subsequent coronal flow back off the highly charged antenna body... We know that the antenna is a "convertor", that is it converts a moving electron departing the antenna into a photon - and vice versa - causing an RF signal in the process...
Certainly, this topic of the role that coronal discharge v/s the charging mechanism plays in antenna noise would make a good dissertation subject for a PhD thesis... Doctoral candidates out there, hint, hint!...

Denny:

I am one calif born and raised boy who has only been though other states on visits only lasting weeks, or passing through. I find the subject quite interesting and have never had to deal with this on a level which has been aggravating or annoying.

Indeed, the worst experience I have ever had is crossing nylon carpets on very dry days in well insulated footwear. However, I have heard horror stories of purplish cornea discharges from antennas which are a sight to behold.

Just as in school, each new generation learns, this is one calif boy who is new generation in his 50's! (and I hate faq's!)

Regards,
JS

One wonders if only nitrogen and oxygen molecules
rubbing on copper can cause that effect.

He shouldn't have potted it. Just use a mechanism to remotely remove
the ferrite core at 10 meters and insert if for the lower bands!

Helium wells? Naa, they are a myth just like hydrogen wells are, Arnold is just blowing smoke when he wants more californian's using hydrogen cars. At least, I think we still get hydrogen the old fashioned way, by using electricity to break water down into oxygen and hydrogen. And, we still get electricity the old fashioned way, by burning oil in generating plants!

Ahhh, California, the land of smoke and mirrors!

Hi Guys,

No, I am using a 4:1 to feed the horizontal portion of the Windom and a 1:1 ferrite choke balun 10 feet vertically down from there. I have seen some favorable reviews of the design and wanted to give it a go.

My desire was to use items I had laying around the shop from previous projects. I am beginning to see the advantages to perhaps purchasing a toroid for the 4:1 balun.

Well, time to hang this new creation and see how well it works (or doesn't).

Regards,

Chris KC8FRJ

One of the strangest cases of corona that I ever
saw was a ham driving down CA Highway 1 near Monterrey
in the fog. It looked for all the world like he had
a reddish light on top of his whip. The CA highway
patrol even stopped him for it. I don't know if
he got a ticket or not.

Technically, that's an OCF, off-center-fed dipole.
A Windom antenna is fed with a "single-wire
feeder connected 14% off center", according to my
1957 "The ARRL Radio Amateur's Handbook". Just a
little ham radio trivia FYI.

Tough to do, today. In a number of states, Illinois being one, new developments are required to have HOA's with a standard, boilerplate CC&R statement provided by the Assembly for simplicity.

Pre-existing non HOA communities are forming HOA's to protect themselves from intrusion by commercial interests that cannot get traction in other HOA communities.

AND...in at least two counties, here, there are basic CC&R's in place on undeveloped land, levied by county boards, in speculation that developers may wish to move that way. Meaning, you can buy a piece of land in deep weeds, build a home with your own hands, and before you close the door, be in violation of antenna restrictions. Even though the nearest neighbor may be an hour away.

Rejecting HOA communities, today, may mean having to move a half a continent away.

You can't even homestead property on the tundra, anymore.

Cool idea! Use some sort of mechanical device, servo, solenoid, screw,
to apply and withdraw the ferrite core.

Worth some play time later down the road.

Chris KC8FRJ

That's a good question. I don't believe it was in place when I
bought my house eleven years ago. But I've been hearing it now for a
number of years from sources within both the real estate community, and
media.

As usual you are technically correct. Then again a Windom is a OCF being feed open wire style, one wire that is.... :-)

Much earlier in my radio days, our Scout Master set up a pseudo Windom. It was an OCF feed via ladder line. This ladder was coupled to 75ohm coax via a 4:1 balun. Stray RF entering the shack was a constant problem. This is why the design of this OCF caught my eye, using a 1:1 choke 1/4 wavelength down the feed line for 15 meters seems like a good idea.

Just seems to be an evolution via good ideas being applied to already good design.

Regards,

Chris KC8FRJ

If the CC&R is "provided by the Assembly" is that to be understood as an agency
of government?

3772. Re: Off topic vernacular designed to irritate others

Cecils' comment goes directly to the issue.

A WINDOM is a 136 feet long antenna that is fed 36% off center with a SINGLE
WIRE against ground.

No balun is necessary!!

Heck, no coax is necessary; or, no twin lead is necessary! Just a wire.

Anything advertised as a coax fed windom is NOT a WINDOM!!

The Assembly is an agency of government, yes. The boilerplate CC&R's provided, as I've read them, are provided as a guideline. Local HOA's are free to amend them as necessary, or as desired. Or to create CC&R's of their own.

There are in a number of states, now--Maryland and Delaware among them--agencies of government which, at least in theory, oversee the operations of HOA's within the state, and are the authority to which residents may appeal cases of malfeasance, or abuse. In Maryland, this agency has relatively broad powers, and works quite effectively at bringing errant HOA's into compliance. In other states...not so.

In many states, HOA's, and their oversight agencies, are not aware of the federal exemption protecting TV and small dish antennae, Ham and CB antennae, and--at least in the opinion of a couple of FCC Commissioners--shortwave receiving antennae. It's up to the homeowner to keep current of the regs, rulings and opinions of FCC regarding antennae

for radio hobbycraft. These may be the homeowner's only weapons when the issue becomes heated on the front lawn.

There is a growing number of books out there, today, regarding the gathering nightmare of HOA abuse, offering accurate information state by state, and remedies in the event of abuse. Do a websearch. There's a LOT of information out there.

Your response goes right to the point. If the HOA is from a government entity
the PRB-1 exemption should be claimed and defended prior to purchase.

Absolutely. But how many really know about that exemption going in? And frankly, how many really think about this issue when the realtor is throwing around numbers?

You would. I would. There are others here who would.

But by and large, no. Home buyers, as a group do not consider this issue when making the purchase. Preferring to bitch after the fact.

Then, again, most HOA's that I've gotten to deal with have been absolutely unwilling to both answer questions or provide copies of bylaws and regulations to which they hold homeowners responsible. One former member, here--who worked at VOA for years, is an active ham and SWL--lived under the shadow of an HOA which refused to provide him a copy of the bylaws, even after a ruling in his favor by the Maryland HOA oversight agency.

You're right. Exemptions and unlawful restrictions SHOULD be claimed and defended prior to purchase.

It doesn't happen.

Your radio doesn't actually hear clear down to DC, does it? :-)

The effect is heard as a result of the charge striking the antenna, thus changing the charge on the antenna. As you know, for a given capacitance, a 600 volt dielectric couples charge just as well as a 1000 volt dielectric. In such a case the 'pop' is capacitively coupled broadband noise. But whether the antenna is insulated or not, looped or not, the static noise is due to a rapid (albeit small) change in charge on the antenna being coupled by some means into the receiver.

> I use something called "Quietflex" that has 1000v insulation.
> Most of the precipitation static doesn't transfer to
> the antenna wire while RF waves/photons flow right
> through the insulation with little attenuation. I suspect
> plastic encased antennas are quieter than bare antennas.

Maybe. It would make sense that the amount of static noise coupled from the environment would be proportional to the coupling capacitance. Knowing that charge tends to gather on a surface, the thicker the 'dielectric', the lower the capacitance. A small series capacitor in most circuits would tend to differentiate an impulse, producing a signal which is proportional to the slope of the impulse. With larger values of capacitance the coupled signals tend to follow the input. So although it's not likely that insulation would reduce the number of noise 'events', it is possible that it would narrow the resulting broadband power spectrum. This could be helpful, as long as it narrows it in the part of the spectrum you happen to be using. ;-)

Andy, Welcome to the group.

A lot of people here want to talk about it and find your point of view on CW interesting reading. Just ignore Bill Turdner. Don't let his insults bother you, he likes to act like an asshole sometimes. If the ship he was on was sinking he wouldn't know about it until he was drowning. As far as your view that CW is just a hurdle to getting a license, I vote for keeping the hurdle. At least when they get licensed they have a skill then. To many of them just want to get a license and talk on a microphone. Any CB'er can to that.

3788. Crankup Antenna as Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-12 01:04:23 UTC
From: Jimmie D <jimmiedee@bellsouth.net>
Message-ID: <2enfh.5483$uY1.1344@bignews7.bellsouth.net>
Source record: 48212

I am considering using a crankup antenna as a1/4 wl antenna on 75/80m and was wondering if ther is any history of someone doing this and using the crankup feature for tuning the antenna. My guess is that it would be too difficult to maintain electrical contact between the movable and stationary pieces to be able to do this but still I am interested if anyone has successfully pulled this off and how they did it.

Jimmie

John, I live just a few miles south of San Francisco. I've been living here since the early '70's. My wife and I go up there on a regular basis to go shopping and visit her relatives, who live there. Art was being an invidious pig and I called him on it. Now, Art, just what did you mean by that?

You are correct (as was Cecil.)

I think "windom" has a wide use today and most off center fed antennas
are referred to as windom. Obviously, he would be better using the term
"off center fed dipole" as this link points out:

http://www.vk3eg.org/technical/xlwindom/xlwindomhtm.htm

I remember being stranded at Chicago O Hare airport
because of snow conditions so I wasted time by putting my baggage in a
cart and walked around. While doing this some people were giggling and
I didnt know why until I realised that I had donned a sweater to keep
warm and it had spread across the front
.............SAN FRANCISCO.............
Do you think I went back and asked them why they was giggling?
I knew why..... so I took off the sweater and went for a nice cup of
coffe with a smile to myself. Would you like to have that sweater,? I
doubt it

As I said earlier, it is his choice Over ten or more years on this
newsgroup
I have witnessed a lot of trashing by him and others, but with me
it is going to be different. I can dish it out also..... and with a
vengance !
Again... his choice. I have no wish to join others in this newsgroup
where
crude rudeness is common but it appears that some want the newsgroup
to go that way. As for hobbies antennas are my hobby
so I am not going anywhere.tho others who don't like
it can go where they please.
One day John it may be your turn and you can play
gentleman if you want to because that is taken as a sign of
weakness here leaving you more prone to insults.
Learn fencing before it happens

I have heard it described on Navy ships but I've never seen it myself. One name is Saint Elmo's Fire. Googling for <"st elmo's fire" corona> produces quite a good lot. (Without the word _corona_ you get too many hits for the movie, St Elmo's Fire.")

Was this Marvin the Martian?

Anyway I found that there truly is no such thing as space modulation. It is used to form a concept of how ILS beam patterns are formed and all modulation takes place in the receiver of the aircrafts ILS receiver. A few years ago The FAA dropped this as a way of teaching ILS concepts.

Calm down, Art. Reg Edwards (PBUH) managed to stay in good humor
when he was the recipient of Richard's little bons mots, and you can
do at least as well as Reg in this regard. Chip managed to hold his own
without sinking to the level of a thirteen year old, and you can do that
too. (Although a few of Chip's alter egos were pretty far gone on the
puerile side.) You should emulate Cecil. He has the
hide of a Texas rhinoceros and never loses an argument (he never wins
one, either). As for your feelings about San Francisco, it's not like
you think it is, and even if it were, at your age no one's going to
ask you to play drop-the-soap no matter how eager you might be to
join the fun.
73,
Tom Donaly, KA6RUH

Actually, at the time I typed that, the thought rattled through my head
that I ought to set up a wind tunnel (ala the Wright Bros) and test to
see what the difference is between dry, charged wind and the same with
dust in it... Then the reality that there are only 29 hours in a day
popped up...
Had I followed my druthers I would have wound up a professor of
physics, or some such, at some minor university where I would have made
the doctoral candidates lives miserable by insisting that they do their
dissertation on such real world stuff instead of the meaningless trivia
that most dissertations I have read in recent decades represent...
Probably it is far better for them that I drifted off into the dark
side of the force, instead..

Dunno why it is in Texas as opposed to Siberia, or the Antarctic
<actually we haven't really checked there, have we?>, or in deep wells
along the equator... Anyway, the book ATOM gives a great, pop version
of the cosmology of the elements and why Helium is here and there... I
don't necessarily buy into his version of cosmology and that the Big
Bang is the end all and be all of the universe, but he does a bang up
job of presenting it...

Jim Kelley wrote:
> Your radio doesn't actually hear clear down to DC, does it? :-)

Doesn't matter since I can't hear DC anyway. If the
charge striking the antenna is a DC pulse, part of
the released energy extends into the RF region whether
the event is linear or not.

> The effect is heard as a result of the charge striking the antenna, thus

> broadband noise. But whether the antenna is insulated or not, looped or
> not, the static noise is due to a rapid (albeit small) change in charge
> on the antenna being coupled by some means into the receiver.

Your idea assumes linear displacement current, i.e.
charge transfer around the dielectric. My idea assumes
charge transfer through the dielectric, i.e. a tiny
nonlinear breakdown of the dielectric. We can haggle
over the exact physical mechanism but the result is
probably the same in either case and maybe a combination
of the two. The thicker the dielectric coating on the
antenna wire, the lower the precipitation noise from the
antenna. That has been proved to be true for airplane
antennas moving through air. Seems relativity would hold
true for air moving past antennas.

> It would make sense that the amount of static noise coupled from
> the environment would be proportional to the coupling capacitance.
> Knowing that charge tends to gather on a surface, the thicker the
> 'dielectric', the lower the capacitance.

It would also make sense to say the thicker the dielectric,
the smaller is the chance of a nonlinear event. I sure wish
I had not kissed my girlfriend on her ear ring 50 years ago
after sliding across plastic seatcovers wearing wool pants.

So is precipitation static a linear or nonlinear event? Or
a combination of the two? Does it matter?

I suppose if it fits you then you blend in and are accepted
I didn,t want to be accepted I suppose don't ask don't tell rules

>Richard, we get bored at some of your comments

Hi Art,

I can also see that you are bored with antennas, especially:

>> Center Frequency of use 14.25 MHz
>> element length height
>>
>> 1 209.46 927.1 feed element
>> 2 198.25 973.97
>> 3 172.78 822.86
>> 4 219.83 964.4
>> 5 185.53 922.4

Did you get bored with a gaussian bundle?

When I threw 4 of the 5 wires away, the gain sprang right up and it
came closer to match. But that would make it inefficient, wouldn't
it?

Hello Owen, excuses for the delay, because I was caught by a very bad
cold...

> Your design is for an o/c stub. Haven't you modelled a s/c stub by
> connecting the transmission line to W998?

No, at least it was not meant to be. When TL cards are specfivied
without
additional real- and imaginary shunt admittance values they are to be
considered as an open end, although a dummy wire/segment is need
for connecting the TL end.

> I have checked your proposed design on Winsmith, and it gives a 50
> ohms input impedance.

Aha, nice to know. It seems the Cebik program is not in error.

> Nevertheless, it is hypothetical as it is not
> practical to connect a 300 ohm stub to 50 ohm line, 50 ohm line will
> be coax (in practical cases) and it is not practical to make a 300 ohm

> balance issue that you have not dealt with in your model.

Yes, I know.

Who told you that the 50 ohm line was not symmetrical... (hi, hi, joke)

> The other thing about the design is that two of the transmission line
> elements are very close to 90 deg in length, which means that
> operation is very sensitive to frequency change.

That's an interesting aspect of the situation.

> If you really want to make a 40m inverted v work well on 80m, you
> might have to match at the feedpoint. It is hard to get an unloaded
> dipole of length 25%wl to work well without matching at the feedpoint.

The specified problem was only hypotetical, and does not exist in real
life (at least overhere).

Thank you, and the other posters, for the feedback,
Arie.

What I don't understand Tom is that Richard has a brain and yet he stoops to this kind of behaviour which is usually the path of people incapable of individual thought. The latter I sympathise with and do not feel the need to respond to and ofcourse there is always the evil person lurking around that is filled with hate.For my part I was astonished as to how this group regarded the idea of a diiferent antenna aproach which has now been accepted by better qualified people that you find on this group. I have spoken to people who have known Richard and all say the same thing he is discruntled with life and .. well I wont go into that.But even as amateurs we are all interested in antennas and when yet when one comes along it is rejected without one iota of intelligent educational discussion or thought of delving into just a cacaphony of insults from those who have mistaken anticipation that all is known, at least with this group. Not everybody has the opportunity of getting an education and many are not capable of absorbing it thinking that they know everything that is important. Ofcourse when you read about it you can always take the stance that Roy takes i.e. I don't understand which can change later when it becomes more fully understood. Amateur radio is a hobby for all types of people mostly old guys angry at the thought of change or dying but that is not a reason that thinking people can't get together and discuss a niche in the hobby in the search of knoweledge knowing that knoweledge alone does not lead to miraicles. Sometimes this group reminds me of a statement I heard years ago.

Richard you can't change your spots that quickly. I am confident of what I was talking about
and I know you have a brain so I need some convincing as to what you are really up to before I respond in kind. You have turned so many times as you have drawn me into discussions that I have no interest in joining you down there in digging a hole since life is good from where I stand. I tried sharing and it didn't work so you can write a critical article after you read what I have found. Your confirmation is not important in my life.Why don't you dunk my posts so this silliness can come to a stop? Find your jollies elswhere.

3829. Mystery antenna problem

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-12 17:51:22 UTC
From: Michael Coslo <mjc5@psu.edu>
Message-ID: <elmq6q$13du$1@f04n12.cac.psu.edu>
Source record: 48103

After the bout of windy weather we had a week or so ago, my mini antenna farm was wrecked. My HF6V sustained a broken mast, which was easily repairable.

My OCF dipole on the other hand, stopped working properly.

Originally cut for the standard 80-40-20-10 config, the best SWR near 80 meters has risen to around 4.37 MHz, 40 meters is around the correct frequency, but has SWR has risen a bit to around 2.5. 20 meters is over 3, and 10 is better than 7.

18 MhZ also has a 1.2:1 SWR.

SWR measured with a MFJ259 meter.

The specs of the antenna are (roughly, as I'm doing this from memory)

48 feet short side, 130 long side

4:1 Balun

Height around 50 feet.

Coax coiled balun near house entrance Coax split just above balun for lightning arrester installation.

Since I bought a new 4:1 balun at Dayton last year to replace one that I fixed a while back, I decided to replace it. Same result.

I took the choke balun and lightning arrester out of the picture to isolate them, and measured from there. No difference.

Coax connectors look good.

So what I am left with is the coax and the antenna wire itself.

Unless someone has played an *awesome* practical joke on me, the antenna dimensions haven't changed.

So can coax go bad in a way that will raise the lowest SWR in the way I describe? Of course I could just replace it, but I'd like to know why.

Hi Mike,

You do not mention what type of Coax /fittings your using But I've had the foam insulated type change in high winds here in the past. Also was there any driving rain with the wind.. check for moisture penetration at the connectors. if moisture has gotten into the coax braid it may produce the results you speak of also.
good luck
73 Dave Kc1di
let us know what you find :)

Cecil, you don't have to postulate a non linear breakdown within the dielectric to explain the transfer of energy from the charged particle striking the surface of the insulation to the free electrons on the wire... Capacitance will handle that nicely... As you stated, a thicker insulator makes a quieter antenna under static conditions... Capacity effect would seem to answer that...
If you don't like that, a charged particle striking the dielectric surface suffers an abrupt change in motion... A charge changing motion has it's own method of talking to us...
And, lastly, we have not roundly beaten the water droplet for dripping off the antenna and taking a charge with it...
"Bartenner, I'll have one, hic, for the road."...

Hi Art,
One of the most difficult things in life to do, for those
blessed with a creative mind, is to learn how to communicate
ideas to those who are not similarly gifted. Your ideas are interesting,
but in order to appreciate them one has to learn to think in a
different manner with a different part of the brain than most
people are accustomed to using. You should be more pitying than
angry at those who don't understand. Just inventing something
isn't the end of the process. Explaining and defending are the
hard parts. You can do this better if you don't allow yourself to
be riled by those who don't agree with you.
73,
Tom Donaly, KA6RUH

If that was the test you took it explains a lot.... It sure explains why you are so fearful of the CBers taking over. You never passed a valid exam, so you might want to turn in that ticket and try again. Let me know where you are and we will find you a testing session close.

We still don't have your call there SC. I'm thinking that you may not actually have a call and are just jealous of us folks that passed the tests.. (Grin)

So Art, I take it you are impling that people from San Francisco have
something to be ashamed of just because they are from their or even people
who visited there should be ashamed of having visited there. Whats your
problem with SF, its a wonderful city.

No they are not, at least to this group. When I share my thoughts it
only takes one posting before the onslaught starts. If there was any
interest one person would have said hold on Art explain such and such
before you move on but that sort of thing doesn't happen because
peoples minds are closed but they also want to be heard. Look at Slow
code frankly I think he is suicidal and grasping at straws so he can be
helped in some way.There have been many experts that have fled this
group and it is leaving a void. Sometimes when I want to share an idea
I am looking for further knoweledge on the subject to see where I went
wrong, in other words to get honest debate going which allows one to
tolerate the other stuff.
The name of this group implies debate on antennas but some see
different things that attract them to this group and for me it is not
getting that hard to see.
Seems like every day you hear.....Lets get ready to RUMBLE.
Go back to my last thread and then judge if what I am saying is true.

And you know what over the years it has just been three people who gets these personal assaults going, two of them have brains and the other just likes to swear and argue and threaten people.as far as brains he states he has them but wont show the evidence

Jimmie, thank you for your consideration, thank you for the award
thank you for posting and sharing your thoughts
Now about your antenna or do you prefer to stretch this thread out and
string everybody along with you?

Hi Denny,

Lack of shame does not bring notoriety like it used to. That coin,
which was SOP inside the beltway, has lost its glitter. You have to be
more creative:
A convertor consists of a resister, capaciter, and
inducter expressed in terms of a gaussion sweater theory.

What would yo Mama say 'bout that?

Cecil, can you state that if an antenna is in the house one would not
hear static?
I seem to remember that when I was at the top of a mountain in a rain
forest I put the antenna inside the car but the noise was S9 plus....
no communication could get thru
Bearing this in mind static noise was radiated to the antenna was it
not? So why cannot a droplet falling at 32 ft per sec sq not produce
radiation or if it impacts a dielectric transfer a electric charge with
curl? Isnt this lightning on a small scale? What I am getting at I
suppose
is if the antenna is protected from the environment and gets static
noise surely it is a radiaated phenomina. IR antennas have never stated
that their antenna was immune to static!

From: Jimmie D <jimmiedee@bellsouth.net>
Message-ID: <vjKfh.189$Cv1.65@bignews6.bellsouth.net>
Source record: 48120

This afternoon while cleaning a closet I pulled out an old US map that had been marked with contacts I made back when I worked 10M a lot. After the local stations there is a big empty area on the map then I started making contacts again at about 300 miles. Antenna used was a 1/4 lambda groundplane with the radials drooping so to match 50 ohms. A chart I found indicates that this means I have a vertical angle of radiation of 50 to 60 degrees. Is this correct??. I didnt think the angle would be so great for this antenna.

BTW the antenna was about 30 ft off the ground when in use.
Jimmie

The gap between the farthest of the ground wave contacts and the nearest of the skip contacts is termed the Skip Zone and the 50 to 60 degree number you cited sounds accurate. It represents the highest takeoff angle that is successfully refracted back to earth.

Please note there is no one takeoff angle. It's a range of angles and your transmissions at many angles are returned simultaneously. A quoted takeoff angle is merely the angle for the strongest signal. For a given paths a particular takeoff angle may be optimum, but others will still work.

Would the skip zone (the gap between where ground wave peters out and
where sky wave is sufficiently low angle to refract in the ionosphere)
explain your observation?

Hi Jimmie,

Fresnel? Why not a non-linear medium yielding a Kerr Soliton?

Having said that, what does it:
1. Demonstrate?
2. Prove?
3. Bear any relevance to?

Grab any equation and you can tweak it until it fails and a new
physics is born.

This is turning into a rice bowl that feeds the multitudes.

Yes but the chart I have seems to be telling me that the distance to the
first skip zone has a direct correlation with radiation angle with 300 miles
being indicated for an antenna with a 50 or 60 degree angle . Is this
correct? I was thinking this particular antenna would have a lower radiation
angle but I am beginning to think this may be typical of the drooping radial
1/4 wl antena.

Makes sense, since as I get further away, 600 miles the density of contacts
actually increases.
Seems to be a really strong concentration of contacts in gulf area from
louisianna on toward
texas from here in north carolina.

J,

If I treat the earth as flat, and figure that the propagation is via
F2 layer, say at virtual height 300km, the the rise is 300km for a run
of half of 300mi, or 240km, so the angle of departure is 51 deg.

The refraction mechanism is sharp cut-off, higher angle of incidence will not refract.

We don't know what the pattern on your antenna is, but even though it may have some sharp deep nulls, it is most unlikely to exhibit a total cutoff above that 50 to 60 degree number you have proposed.

Antenna patterns influence things, but exceeding the MUF on a path assures you of no propagation, the MUF dominates. Sure the MUF varies over time, but your historical observations probably just capture the highest MUF that occured with some small probability, depending on how much time you put in to collecting the QSOs.

Owen

Hi Jimmie,

The drooping radials affect match only (classically so). The relation
of the WHOLE antenna to ground is the significant predictor of
radiation angle.

John Smith mentioned the Microvert antenna, which I know
very well.
I made an extensive comparison of the RoomCap (hb9abx)
against Microvert, and was using the best Microvert available
(MV-500) for 40m.
Test at same location, both antennas at same height in
A-B configaration.
Test was performed by many rapid changes between the
two antennas, and the remote station was observing
the signal strength.
Result was, that the RoomCap was 2 s-points stronger
in average, in receiption as well as in transmission.
Rember that 2 s-points correspond to 12 dB.
A very clear result.

Hi,
I am needing to build a VLF antenna for my Andrea
RAK-7 receiver. This receiver covers from
16-600 kHz in 6 bands(15-25 KHz, 25-43.5 KHz,
43.5-77.5 KHz, 77.5-153 KHz, 153-308 KHz,
and 308-600 KHz).

I was wondering if anybody here could help with a
simple yet effective antenna for this receiver?

I am limited
to what's in my small junk box.

I actually have all of the parts to build an E-probe
except for a couple J310 and 2N5109 transistors and a
couple 470uH chokes.

This will be my first venture into the VLF world.
Any help with this would be greatly appreciated
Thank You

Hello Richard,

The quarter-wave ground-plane antenna's vertical radiation pattern
approaches that of a half-wave vertical as the radial droop approaches
90 degrees, while the feedpoint height remains fixed. Whether one views
that as significant is subjective, of course.

73,

Chuck, NT3G

I can state that if an antenna is in a closed house one
would not hear *precipitation static* which by definition,
involves charged particles. Here's the definition.

http://www.atis.org/tg2k/_precipitation_static.html

But there are lots of other kinds of static. I just heard
on The Discovery Channel that a certain percentage of the
static we hear is left over from the Big Bang that happened
some 12.5 billion years ago. There's lots of static here
in East Texas, mostly from lightning and old power line
equipment. I have never noticed precipitation static in TX
or in CA. But it was overwhelming in the Arizona desert.

3863. Image theory

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-13 13:18:21 UTC
From: David <nospam@nospam>
Message-ID: <QLKdnXteOa4HYOLYnZ2dnUVZ8tOmnZ2d@bt.com>
Source record: 47937

Image theory is used to justify the idea that a ground plane reflects the radio wave emitted by a vertical monopole antenna. The radio wave emitted by the vertical induces currents in the metal ground plane. A charge on the vertical induces an opposite charge in the ground plane. If charge on end of vertical is +q, then it induces a charge of -q in the ground plane. The effect is that the charge -q appears to be a distance below the ground, the distance being equal to the distance between ground and charge +q above ground. A distibution of charge is induced in the ground plane by the radiating vertical.

With a dipole the electric field lines go from +q to -q. If a ground plane is inserted at the zero or middle point, with charge below ground plane removed, the electric field lines above the ground plane stay the same. The metal ground plane is a pool of electrons that adjust so that the voltage at the surface is zero i.e. tangent E = 0.

Four radials form a counterpoise. The counterpoise has currents induced. These induced currents then re-radiate, altering the radiation pattern and inducing currents back in the vertical. The induced currents in vertical then affect antenna impedance.

A counterpoise is a metal conductor that has currents induced in it by the radiating element. The currents re-radiate resulting in a field distribution where the countrpoise is a mirror image or opposite version of the radiating element.

What surprises me is the claim that the ground plane can mirror a 3D image e.g. a stacked Yagi.

What are your views on above?

Why do some articles say that the ground plane needs to be connected to the outer braid of coax, while others says this is not necessary?

Every antenna has a vertical beam width. For Vert1.ez
that comes with EZNEC, the 3 dB vertical beamwidth
goes from 9 deg to 53 deg with maximum radiation occurring
at 26 degrees. The vertical beamwidth on a vertical
creates a doughnut of coverage for the first hop. The
inner circle of your doughnut was at 300 miles where
your radiated power may have been more than 3 dB down
from your angle of maximum gain. Question is: Where
was the outer circle of your first hop doughnut?

Source record: 47940

An earlier posting said that a magmount works because the coax braid (rather than the metal body of the magmount) capacitively couples to the car.
If current flows on inside of coax braid, and braid is an effective shield, how can the braid capacitively couple to the metalwork of car? Either the braid is shielding or capacitively coupling but not both at same time?

Perhaps capacitive coupling is from open unshielded body of magmount, and coax braid adds to area of 'capacitor plate'.

However, the metal body inside the plastic cover does seem rather small to capacitively couple to the car roof especially for HF.

Let's look at two equal radials, 180 degrees apart,
horizontal in free space. The radial currents are equal
in magnitude and opposite in direction, i.e. differential.
Theoretically, this causes considerable cancellation
of the radiating fields of those two radials. EZNEC
confirms very little horizontal radiation from two
symmetrical horizontal radials in free space. The same
thing holds true for symmetrical top hats.

If the coax braid is coupling much RF to chassis ground,
then the capacitive coupling provided by the magnets is
too small. That tends to happen when magmounts are used
on 75m. I will make some common mode current measurements
for magmount coax for 75m and 17m and post them here.

What is missing is the altitude of the reflecting zone. The altitude of the E, F1, F2 layers very greatly depending on solar activity, season and time of day. There are so many variables in propagation that is is impossible to definitely state what the path and angle were.

I have a tubular crank up as you describe. I have never even attempted
to use the tower as a radiator because of the number of for seeable
problems. Since it is grounded, a shunt feed of some sort would be
required. It seems that anything that changes on the tower requires a
corresponding adjustment in the feed.

The raising scheme in my tower presents an unpredictable electrical
bond in the structure. I don't think minute to minute conditions are
predictable.

I considered a steel tape measure alongside the tower as a radiator,
but the model of a grounded structure did look promising!

A remote antenna tuner might show some promise but I will shy away
from it for fear of damaging the electronics with a rapidly changing
load.

As long as there is a need to raise & lower the mast anything
(dipoles, inv v, etc) are messy when lowered.

I consider it essential to be able to retract my tubular mast with a
Cushcraft A# on it!

Hmm, all this presumes that whip is the radiator and the car is merely
the ground return for the radiated RF currents...
What happens if we change our point of view and say that the whip plus
car is all part of an off center fed dipole that is insulated from the
earth by rubber donuts, and the RF currents on the external coax are
merely the equalizing flow of RF returning via unequal capacitive
coupling of the car body and whip to the earth? At that point we are
measuring the return flow between two unequal halves of a dipole...

Assume an ideal vertical antenna with elevated radials
fed by coax with no common-mode current on the coax.
Install a large meshed variable capacitor between the
coax braid and the radials so nothing really changes.
Then start reducing the capacitance to the point where
common-mode current on the feedline becomes a problem.
This is akin to the magmount problem at lower frequencies.
Some solve the problem with a direct strap from the
magmount frame to the vehicle chassis, i.e. by shorting
out that variable capacitor.

Hi David,

There are a lot of mystical assertions made in behalf of magmounts.
You need only closely examine one statement to consider the mystical
quotient potential:

>because the coax braid (rather
>than the metal body of the magmount) capacitively couples to the car.

The "capacitor" is trotted out like it was a mythical animal on public
display. And yet all capacitors have at least two leads. In the
forced arguments of magmounts, obviously one lead is the RF and
presumably the other is the car body. However, those same forced
arguments clam up when the question begs "where do those leads go? (as
all cap leads do eventually complete a circuit to a source).

Very long paths are involved, and those forced arguments failing to
walk that walk (much less do that talk) are not going to explain the
complexities of reactances and resistances that dominate that
dimension.

>If current flows on inside of coax braid, and braid is an effective shield,
>how can the braid capacitively couple to the metalwork of car?

This statement betrays a misunderstanding of the feed point
relationships and the role of Common Mode.

>Either the
>braid is shielding or capacitively coupling but not both at same time?

There is no either/or offered in the first place. Your mistake of
feed point relationships has overlooked the "third" wire of the
seemingly two wire load. That "third" wire (the coax shield) runs in
very close proximity to the car body for as great a distance as any
capacitor lead described above. This shield/body relationship offers
vastly more capacitance than any mount.

Review that archives for discussions of the need for feedpoint
decoupling, Common Mode, Chokes, and 1:1 BalUns. This study will
correct the mistake of feed point relationships in your statement
above.

>However, the metal body inside the plastic cover does seem rather small to

>that as significant is subjective, of course.

Hi Chuck,

Lifting a ground plane off the ground, so that drooping the radials could, in fact, be drooped; this does more to raise the gain, than drooping the radials (something like four-fold more).

Already having the antenna off the ground, and then drooping the radials does accomplish a lowering of the angle, and increasing the gain. However, I would propose drooping is largely practiced more to pull the match into 50 Ohms from 35 Ohms than for any perceived benefit in "Gain" (which is perhaps all of half a dB or slightly more). Changing the height could easily erode that partial dB.

Moral:
Droop the radials for match;
Raise (correctly place) the antenna for gain.

>vastly more capacitance than any mount.

The "third wire" (being the current flowing on the outside of outer
conductor of the coax) is more properly a transmission line itself,
possibly a leaky (ie radiating) transmission line.

For example, were you to place a magmount on a large metal ground
plane (that is a sheet, not wires), and lay the coax straight from a
magmount to the source whose ground terminal is bonded to that ground
plane, the effect of the coax will depend on the electrical length
formed by the outside of the shield of the coax and the ground plane.
Consider the effects of the transmission line so formed were it an
electrical quarter wave, and an electrical half wave (taking into
account any bulk shunt capacitance at the magmount due to the mount
itself..

Who knows what happens in actual magmount installations? They truly
fall into the category of "works" on lower frequencies, whatever
"works" means to the individual.

Owen

The books also say that if the antenna is vertical to groundplane the iamge is in phase and reinforces the wave emitted by vertical.
If antenna is horizontal and close to ground plane, the image cancels out wave emitted by antenna.

Is this what happens in real life? It is known that if the 2 conductors of twin feeder are close together, the fields cancel out and there is very little radiation.

Are you saying that electromagnetic theory is wrong? What about fibre optic cable? If ordinary glass strands were used, when the cable was bent, the light would be blocked and not travel any further.

I've recently dug out an old groundplane antenna I built years ago to play around with. I've lost all my old papers and haven't been able to find the tuning equation for setting the proper angle of the base emitters down from the verticle emitter to a certain freq. Setting the lengths is no problem, it's the angle I haven't found. I believe I originally pulled them from an old Satellite Times Mag about 15 years ago which has long since gone the way of the wind. Would anyone lend a hand?

Ah, another foray into cosmology - and here in a rain static thread!

The BBT is indeed venturing further and further into the land of "just so",
and reasonable thinking people and not just RWC fundies (who do not think)
can legitimately find some problems with it.

I still await proton decay. But I have a gut feeling we may not find
it.....

Hi OM,

Actually, the lengths and the angles BOTH impact the resonance and the match (varying from 30 odd Ohms to 70 odd Ohms). One solution is to cut the radials and start depressing them until you get the match you want. If they don't match, cut them shorter and repeat.

Hi David,

Your sources are pretty crummy. This information is quite in
contradiction with the operation of a halfwave horizontal a
quarterwave above earth, isn't it? A simple EZNEC model will reveal
this clearly.

>Is this what happens in real life?

Umm, no.

>It is known that if the 2 conductors of

I've worked with a lot of fiber optics, and that statement simply
doesn't make much sense. Ordinary and un-ordinary glass (as well as
plastic) strands work differently by degree, not differently by
theory.

The question to me is not whether or not that the phenomenon exist but that it does seem to behave differently at different places at least per the different reports I have heard here and my own personal experience. In some places it is quite common and in other places people are totally unfamilar with it. The latter would have been my case if I had never moved from South Ga. From my perpective it does seem to track humidity or rather the lack of humidity. IS this not correct?

3897. E/H in a waveguide

Message-ID: <45812a0d$0$1014$39cecf19@news.twtelecom.net>
Source record: 47970

If possible i wish to know if in a waveguide it is E/H = Z=377 Ohm ,or ,as i suspect , the impedance migh be may quite very different from such value , in a manner that the mode TEM can have it at least E/H= 10000 Ohm too.

Thanks

i'd guess you won't really know w/out a detailed physical inspection
unless somthing happens drastic when it rains vs a long dry spell

sure the coax could have gone bad but you have a nice meter seems you
could actually test it ,

any chance animals chewed any of the coax did anything touch the
raditors such as a branch or such perhaps near a endpoint tie off?

prb i am not much help but good luck

Creationist? Me? Surely you jest, Shirley... I am not superstitious... Well, a little knowledge is a dangerous thing, they say... And in a lifetime of accumulating a little knowledge I have noticed a few things along the way...

FIrst mathematics is simply a language, just another way of describing things... And when I was a majors candidate in science I noticed when taking math that equations can describe things that cannot exist in the physical world... I remember one physics course where the instructor, droll fellow by the way, 'proved' that the universe is multidimensional (Fime, Superstring, etc.)... His equations balanced on both sides and therefore it had to be true, so he said...
At the same time I was also a majors candidate in the Arts and I had noticed this priceless contribution to another world of language:
`Twas brillig, and the slithy toves Did gyre and gimble in the wabe:
All mimsy were the borogoves, And the mome raths outgrabe.. . . ',
etc...

Now I gotta tell ya, as a farm boy from the thumb of Michigan I have pitched my share of manure and know it when I smell it...

Lastly, we have to be careful of falling into the trap similar to a former Director of the Patent Office who declared everything important had already been invented... It is easy to simply fall in line with the big names and big reputations declaring that the BBT explains everything and that settles that... There is science and technology yet to come that will find distance, forces and energy in the universe that is likely to turn the BBT onto its ear... So, for the moment I remain a thoughtful agnostic RE the BBT...

denny

Of course that's correct. Take a look at table 2 in
the following ESDA web page where there is up to a
60 to one difference in static levels between 25% max
RH and 65% min RH: They also say, "Virtually all
materials, including water and dirt particles in the
air, can be triboelectrically charged."

Scientists once said space is not empty. Then some other
scientists "proved" that space is empty. Now some latter
day scientists have pretty much proved that "empty" space
is not empty.

It is possible that ordinary black holes eventually
explode forming mini-universes (like ours?) So maybe
it was just a Relatively Medium Bang instead? Would you
believe an RMBT? :-) These multiple bubble universes
may sometimes collide and indeed there seems to be a
section of our universe where the light is blue shifted.

Hi Jimmie,

The difference is, if you have the instruments suggested in these
articles offered by Tom, then you have a basis for making
determinations. Anything else is the subjectivity of stamp
collecting.

Humidity is a correlative, certainly. Temperature and water content
are strongly linked, but most of us are only aware of RELATIVE not
absolute humidity. Hint: using the right instrument can make a huge
difference in this issue of Rain Static.

I doubt it has anything to do with efficinecy, but rather criticalness of
the dimenions at 23cM. In addition, a 0dBd horizontal antenna at 1296 is not
all that useful.

Hi "ml"

If you want hemispheric coverage of circular polarizes signals, I have documented a concept that involves harnessing 4 half wave dipoles to provide excellent coverage. For low power situations regular TV quality components can be used. The concept can be seen at http://213.250.83.83/~jerry/.

as i pointed out before, and this verifies, you have found one of the
limitations of finite element methods for modeling antennas. very close
spacings between long elements causes un-realizable results. the extremely
low real components of the impedance and high reactive values are symptoms
of this.

this is true for any array.

define 'gaussian array' as it applies to antennas that you are describing.

that type of array is not defined in my copies of Jackson's or
Ramo-Whinner-VanDuzer's books, nor does my IEEE antenna design handbook
mention that term. there are references to 'gaussian beams' with respect to
the shape of the fields from feed horns for microwave dishes and other
quasi-optical systems. Some searching of the web also seems to refer to
gaussian arrays, but those all seem to be related to current or power
distribution on elements of an adaptive array.

> 73,
> Tom Donaly, KA6RUH

I want to thank Tom Donaly for mentioning these articles. I worked very hard of them back when I used to write for Scientific American and I still think these are great resources. "Getting a Charge Out of Rain" is actually my favorite of the projects, and it's one I invite everyone to try. The apparatus described in the article allows one to measure the electric charge on individual drops of rain as they fall in a summer storm.

The instrument set a new standard for measuring charges on droplets because the device is intrinsically calibrated. The calibration is achieved by using a precision capacitor. Since the value of the capacitance is precisely known, the charge on the falling drop can be determined by simple geometry and the size of the voltage pulse generated as it falls through the detector. As I understand it, some folks who do these kinds of measurements professionally redesigned their detectors to take advantage of the technique that this article introduced.

If you can't find a copy of these articles in your local library, they are available on The Amateur Scientist 3.0 CD-ROM, which is my personal archive of all the articles that ever appeared in The Amateur Scientist department of Scientific American going back to the beginning in 1927. (Over 1000 projects.) You can find it either on Amazon or on my own web site at http://www.brightscience.com

> myself even tho no facts only words have been offered

unfortunately it is not possible to prove a negative. and you have not proved your case. I have pointed out the well known failure of finite element modeling that most of us with engineering degrees do understand and avoid. you have simply been misled by software that you don't understand completely. And no, I don't think everything is in books already, but I don't believe that someone playing around with software they don't understand is going to discover a new principle that hasn't been studied elsewhere. So, again I ask, please define 'Gaussian array', give web references that explain it if you can't, surely something that is on the cutting edge of technology will have many web sites trying to promote it, or sell antennas based on this design.

3916. Critical Frequency and MUF

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-15 00:41:33 UTC
From: "C. J. Clegg" <reply.in.group@nospam.no>
Message-ID: <pan.2006.12.15.00.41.31.358554@nospam.no>
Source record: 47990

I thought I understood about critical frequencies and MUFs and such, but an event this evening has me puzzled.

I was on a military net on a frequency somewhat above the 75-meter band. According to the "Near Real Time F2-Layer Critical Frequency Map" at http://solar.spacew.com/www/fof2.html, the critical frequency in this area at that time was below 3 MHz, which would have put it WELL below our frequency of operation. Yet, I was able to communicate with another station about 70 miles away, with weak-but-clear (Q5 copy) both ways. And I'm only running 5 watts (he was running 100 watts I believe).

70 miles seems a bit far for groundwave, and the critical frequency seemed much too low for NVIS, so how was I able to communicate reliably with this other station?

My antenna is a half wave dipole for the frequency in use, at elevation 17 feet above ground. My ground elevation is about 250 feet above sea level.

Would that big solar storm of the last day or so, the one that made all the news about how it might knock out satellites and power grids and such, have anything to do with it? I would have thought that if anything, that would have hurt not helped.

Seems very strange...

Hi Shawn,
I found the references on the CD-ROM. I can attest to the

fact that the CD-ROM is well worth having. The old Amateur Scientist was a wonderful feature of Scientific American. It would be good to see it resuscitated.
73,
Tom Donaly, KA6RUH

3918. Re: A request for guidance from academics

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-15 01:02:36 UTC

Source record: 47992

electrostatics is a small subset of electromagnetics, and with good cause. its application is limited to static electric fields only. no current, no radiation, just static electric fields. so don't try to sell an antenna based on electrostatics or you will be lumped in with the e/h guys.

coupling between elements of an antenna is a given, you can't have a conductor in an electromagnetic field without it coupling somehow to the field and re-radiating. to try to convince anyone otherwise is to ignore 100+ years of electromagnetic research.

also, if you are basing this on new principles you can't expect eznec or ao or any of the existing finite element programs to do anything reasonable for it, they will all fall apart like the example you posted and give unobtainable models because they use classical electromagnetics to do all their calculations.

as far as patents... i don't trust them any further than i can throw them, you can patent anything unless it says 'free energy' or 'perpetual motion' in it. heck there are even patents for faster than light antennas. if you can't explain the principles well enough to pass a peer review for something like the ieee a&p proceedings the science isn't right.

i would not call that far for ground wave if the band is reasonably quiet.
but also the very disturbed conditions could have greatly enhanced the muf
locally, there is a great auroral opening on 6m now and also some sporadic e
enhancements reported due to the storm, so it could have been some of that
helping things along.

Do you know what f0F2 was at the path midpoint, or are you depending
on interpolation?

In this neck of the woods, there is abundant sporadic E, and of such
intensity that ionsondes are showing two, three and four
"reflections". How do they measure f0F2 in the presense of long
running high intensity Es that prevent rays passing through to the F2
layer?

Hi Art,

You've repeated my name more times than Gauss.
That sure gives it a lift. ;-)

>Is there any other academics out there that can help me out as well as
>clarifying what I say for better understanding.

The clarification I offered was:
Throw away 4 of the 5 wires and you improve
both the gain and the match.

If you dismiss this as drivel (a perverse contempt in this forum
dedicated to gain and matching) then there is no clarification to be
gained.

As Dave pointed out, submit to a judged journal and show us the
citation when it publishes.

Well, the path midpoint was pretty much straight up, or maybe up to 20 degrees off of vertical. foF2 all along the path was just a bit under 3 MHz. Frequency of operation was well above 4 MHz.

> In this neck of the woods, there is abundant sporadic E,

I don't really know much about sporadic E, have a vague idea what it is and that's about all, but doesn't it assume that there is an E layer to begin with? This was about 7:30 PM, sunset was around 4:45 PM, and the E layer would have been pretty much gone along with the sun, wouldn't it?

As I mentioned to Owen, I don't know a lot about sporadic E, but I assumed that it required that there be an E layer to begin with, and wouldn't the E layer be pretty much gone along with the sun? (this was 7:30 PM.)

Anyway, doesn't sporadic E mainly help higher frequency communications, like 10 or 6 meters or above? This was somewhat above 4 MHz, above 75 meters, considerably below what I would have thought would have been affected by sporadic E. But, like I said, I don't know very much about sporadic E.

Yes and no. There certainly is something termed galactic noise and most of it has apparently been ricocheting around the cosmos all this time. It was first discovered by Bell Labs scientists using a supercooled microwave amplifier whose noise was higher than expected. They covered the feedhorn and lo! ... The noise dropped!

http://www.amsat.org/amsat/archive/amsat-bb/200112/msg00336.html retells part of the story.

There's no way any of us will be affected by galactic background, however, We'd need a system noise temperature better than 3K (That's 3 Kelvin, not 3,000) to detect it. The best consumer LNA's are way noisier. BTW, some parts of the sky are "hotter" than this background level; if we use a low noise TVRO dish system, we could detect a few star clusters. Of course the sun and the moon can be detected.

Hi Art,

D.E. Isbell did this 46 years ago.

>which is a different
>requirement from the Yagi

It has been used for TV antennas for lo those same 46 years and to any
casual view looks like a Yagi.

>where amateurs
>are only interested in gain without due referance to constancy across
>the frequency span
>or with regard to the corresponding beam width

Isbell got that too. It was, afterall, everyone's goal and he got:
1. More gain;
2. Better match;
3. More bandwidth;
than 5 un-optimized wires hanging in the air.

Isbell understood Gaus, Maxwell, McGuffey, and the rest and never
appealed to bundles to explain his design (which really bore no more
relation to his antenna than explaining why a car works in terms of
how zippo lighters create a flame).

D.E. Isbell's antenna is included free as an example with every copy
of EZNEC. It contains 5 wires and exhibits:
1. 10% BW
2. 10 dBi gain
3. a serviceable match

Isbell wrote the design up, submitted it to his peers, a jury passed
on his work, it was published, it was patented (3210767) and it has
stood the test of time.

Isbell also explained how to achieve different:
1. Gains;
2. Matches;
3. Bandwidths;
in terms that others could actually build working models.

In regard to this last, I am sure amateur publications offer simple formula to achieve these goals too.

However, if all one has to read is a book about fields, Isbell's invention may come as a surprise. Ramo and the boys don't really talk all that much about "antennas," so citing them as authorities on the subject makes as much sense as crediting Jane Goodall for the Theory of Evolution.

You missed my point, it isn't so much as the exact location of the
virtual midpoint, but is there an ionosound measureing that point, or
is the map constructed by interpolating measurements from just a small
number of ionsondes, and is the interpolation sound?

I should have added "at this time". But sporadic E is most likely
around the solstices, so you should be seeing a bit in the northern
hemisphere.

3930. Re: E/H in a waveguide

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-15 09:31:31 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <12o4qrmbkv2v16a@corp.supernews.com>
Source record: 48004

Assuming a vacuum dielectric (for which air is a good approximation):

E/H = 377 ohms only in TEM mode waveguides. Can you explain under what circumstances a TEM wave can have any other value?

At frequencies above cutoff in a TM mode waveguide, the intrinsic or wave impedance (E/H) varies with frequency from zero at cutoff to 377 ohms at infinite frequency. Below cutoff the intrinsic impedance is purely imaginary (reactive).

At frequencies above cutoff in a TE mode waveguide, the intrinsic impedance varies with frequency from infinite at cutoff to 377 ohms at infinite frequency. Below cutoff it's purely imaginary.

A good reference is Johnk, _Engineering Electromagnetic Fields and Waves_

A droop of 45 degrees brings the impedance at resonance very close to 50 ohms. EZNEC example file VHFGP.EZ has 45 degree drooping radials. At resonance (around 142.2 MHz), the input resistance is about 51.4 ohms.

No, it's not. An antenna doesn't have a single angle of radiation, but
radiates at all angles.

The image "theory" is a simplification of a problem involving an antenna over an infinite, perfect, ground plane.

Four radials behave nothing like an infinite, perfect ground plane, so the premises upon which the image model is based do not apply. Trying to extend it to such systems as four radials will inevitably lead to seriously mistaken conclusions. The claim about stacked Yagis is just one example.

Roy Lewallen, W7EL

> two antennas. The horizontal antenna is above the vertical, and the
> coax feeding the horizontal runs pararellel with the vertical antenna
> around 2 wavelenghts (24cm) away. My question is will the signal on
> the coax leak onto the vertical antenna?

If you want to make your system sensitive only to one polarization at a time, the first thing you need to do is to prevent any signal from being on the coax in the first place. This can be done by running the coax symmetrically at right angles to the dipole (assuming it's something like a conventional dipole) to prevent current by induction, and adding a "current" or choke balun at the feedpoint to prevent current by conduction.

> I want the two to be as
> orthogonal as possible. I'm not really sure on the physics involved
> but is there a standard seperation that is required to minimize this
> effect or will they always be coupled if I run the lines in this
> manner? Thanks for any info,

You'll prevent coupling by taking the steps I mentioned, and keeping the lines at right angles to each other and keeping each symmetrically placed with respect to its dipole.

Imagine that you have a highly directional transmitting antenna and you spin it at, say, 100 revolutions per second. What would a listener at a fixed location hear? He would hear a 100 Hz (but non-sinusoidal) amplitude modulated signal rather than a constant amplitude CW tone. The shape of the modulation envelope would be dictated by the shape of the antenna pattern. The spectral content, i.e., sidebands, of the received signal would be the same as if the wave had been amplitude modulated by conventional means to produce the same waveshape.

I think that's what they mean.

Thanks Roy, I know but the chart I was using wasnt clear on what it was presenting. It is a photo copied page out of a book and hopefully there was more info that went with it than what I have. The chart does seem to be indicating that one should use the closest skip contacts to get an idea of the radiation angle. It was my doubts about this that inspired my question. Perhaps I am taking the chart out of context or maybe it is just wrong..

After the demise of the old Amateur Scientist column I let my
subscription to The Scientific American lapse and have seen no reason
to renew it, since...

Now, back OT... After getting home last night I was working on a
recalcitrant SG-500 amplifier that wanted to hang up in transmit when
keyed by the PTT, but would not hang up when auto sensing of RF drive
was used for keying... My son opened it up and we removed some logic
chips and using the erasor on a #2 yellow pencil, polished the pins...
Whilst he was finishing that I reconfigured the antenna switch box,
checked the SWR on the 160 meter array and then proceeded to help him
with the amp repair by pointing out that he now did not have a "power
on" light on the amp... While he was opening the amp up again <
patience I'll get to the point in a moment> I spun across the bottom of
160 and listened to a weak CW qso going on.. There was very low static
and it promised to be a good evening if we could get some QRO back on
line...
By now he had found the loose connector inside the amp and reseated
it... We put the amp back on its shelf and connected up... When he
pushed the final coax connector on, the meter on the transceiver went
nuts banging from pin to pin and the receiver was making deafening
popping noises...
"Hey dad, you broke the Orion.", he challenged - he was a bit miffed
over having missed replacing the connector on the amp...
"Mai non, my slow son.", I corrected...
I immediately shut off the power to the Orion and asked him if he had
reversed the power leads to the amp... He indignantly insisted he had
not... He fetched a VOM (which is what I wanted but was too lazy to
get for myself) and proved the polarity was correct... I took the VOM,
unscrewed the antenna coax and put the leads across the PL259...
There was 340,000 microvolts on the connector... His eyebrows went
way up...
"What the hey?", he said...
"It's blowing rain out there.", I said...
"No it's not... It's dead calm out there."
"Go look."
When he pulled open the side door to the shop he was greeted with a
face full of wind and ice cold rain...
OK, now to the point:
There was roughly 3 minutes from the time I was listening to the weak
cw qso to when we unscrewed the coax, and rehooked up to the amp... In
that ~3 minutes it went from essentially no static (well OK, S1-2
static on the meter, which on 160 meters is NO static at all) to just
this side of blowing out the front end of the receiver... There was no

rising static level to herald the approach of a front... It simply was low static until the moment the first gust of wind swept across our fields bringing the rain, and huge precip charges on the 130 foot high antennas...

Do you guys know how to edit a message when you are replying to it so
a reader doesn't have to wade through 3 screens of previously posted
material
to find the section you added?
It really isn't rocket science.

Yes, that's what the TV documentary was all about.

> There's no way any of us will be affected by galactic background, however,

The same TV documentary said that 1/2 of one percent
of the noise on a blank TV screen is caused by background
radiation from the Big Bang. I was reporting what they
said, not what I had measured.

Sounds like you might believe that precipitation
static exists. :-)

Oh, OK, I get it.

I have no idea. I use the map at http://solar.spacew.com/www/fof2.html
and I don't know how they get the information they use to build that map.

Doesn't sporadic E normally affect the higher frequencies, 15 meters and
above, rather than the lower frequencies around 75 meters?

For years I have used Agent for communicating with rec.radio.amateur.antenna. My cable connection is with Brighthouse, who connects with Earthlink for accessing the news groups.

However, on Dec 8 my connection stopped adding headers to Agent. The msg at the bottom left corner of the screen initially says 'connected', but then immediately says 'finished retrieving new headers', but no new headers appear.

I finally found this way to access rraa through a Google entry. Can anyone tell me what is wrong with the connection to Agent through Earthlink for the newsgroups?

Walt, W2DU

Hi Walt,
The problem occurred because you are on a new server, and it has numbered the articles in the newsgroup differently. Most likely your Agent software think you have read (for example) up through message number 20,000, but the new server calls that article number 200. So it thinks you have already seen message 200.

The solution is to unsubscribe to the antenna newsgroup and then resubscribe. Then you can retrieve all of the articles that your new server has.

Hope this helps. And congratulations on the QST article. Very interesting.

Here is an ionogram from the station in Canberra this morning about
1.5 hours before sunrise.

http://www.vk1od.net/lost/ionogram.gif

Note the E layer at 100km height, very well established. It is so
intense, that there are multiple E - earth - E - earth "reflections".
You can see the F layer above it, and f0F2 looks between 2 and 3MHz.

(I believe that the existence of such a strong E layer before sunrise,
and the height in the 90km to 100km range characterise sporadic E.)

Sometimes the E layer reflection is so intense, that there isn't a
hint of the F layer. I don't know how they assess f0F2 under those
conditions, but they still produce the statistics.

I think you may be reading more accuracy into the maps than is safe.

As for "normally affecting higher frequencies", here you can see the
ionsonde discovering the Es layer at up to about 10MHz. When you take
into account oblique paths of a couple of thousand km or more, the Es
here with critical frequency up to about 10MHz should reflect 50MHz
ok. Now exploitation of that depends on such a patch of Es in the
right place, angled the right way, between two stations attempting
communication. There have been some big openings on 6m here in the
last week or so, not huge, just the seasonal openings typical around

the solstices.

sorry, it just doesn't work that way. gauss' law for electrostatics just
can't be extended to handle time varying fields, as soon as you do that its
not statics any more and you have to take into account currents and magnetic
fields which then give you the coupling to the other elements. that is what
eznec and the other antenna modellers make use of... so don't try to model
your antenna with any existing program, you have to come up with your own
model and calculation method to show what it does.

oh, and one important part of a patent is the claims section... what are
your claims for this new type of antenna??

>Walt, W2DU

The news server is busted and the idiots that work there can't fix it!
They haven't add a group in years and have forgotten how to fix it.
I dumped the bums and am now with Worldnet.att
==========
System Status - Details
Last Updated on: 12/13/2006 11:18:22

Customers utilizing Earthlink's DSL and Home phone service may
experience difficulties using Earthlink's News Groups. Our engineers
are aware of the issue and are working as quickly as possible to
resolve the issue.
==========
It went down the 8th and if you call for help they blame it on YOUR
machine. Fxxx them!

Walt:

Set up a news account with news.aioe.org as news server. This is a free
news server and is quite quick in posting/downloading posts.

Even if you fix your present problems, never hurts to have backup.

Regards,
JS

Owen is correct- and anyone operateing 10& 6
meters will tell you the same thing! Have
been on 6 for around 45 years now, an can attest
that "E" openings can occur ANYTIME, day, or nite!
And, the "E" layer is ionized , to a degree, 24
hours per day (There are more than a few running
"Scatter", with power levels of 100-1KW makeing
contacts, when the band(s) are literally closed).
Es is the "bread and butter" of the VHF operator,
rangeing from 35-400 miles for super intense
openings, out to 1200, or so miles, when the band
is barely open. Figure stations (on scatter), from
Montana, New Mexico, Colorado, and Wyoming being
copied with NO major opening, into Reno, Nevada!
And, keep in mind, you also get Double hop, 2
adjacent (or more) layers , giveing you cross
country capabilities. One further thing: IF
you shea short E skip on a band (say 10 meters),
odds are great that 6 is open; Same for 6 meter
short skip, often means that 2 meters, or at least
F.M.Broadcasts (88-108 MHz) will be open!. F2
is associated with sunspots-Es seems to get worse
as sunspot activity increases!Might you find this
interesting? Jim NN7K

Skilled at what? I am skilled at PSK31, MFSK, SSTV, DigitalTV, Packet, APRS, RTTY, Throb, Olivia, Domino, and even CW. So if an operator is skilled in most modes, then they are a skilled operator. You don't have to be skilled in all modes to be a skilled operator.

The EL news server has been bad for months and was down most of the weekend. For months now the completion rate for large binary files has been under 10% and mostly unusable. Some years back I left MSN because they abandoned their news service and went to EL who now seems to be doing the same thing. My guess is that they really don't care because very few of their customers even know what Usenet is these days. I agree with helmsman, go for an outside service...

I buy that. 3K out of approximately 300K on a linear scale is 1%. If it's 50/50 between Big Bang noise and "other," then 1/2 of one percent is spot on.

Thanks.

Good morning, Jim.

What I'm trying to figure out is the effect of sporadic E on the lower bands, e.g. 75 meters.

I was on a military net on a frequency somewhat above 4 MHz and was able to work a station 70 miles away, well after dark when the critical frequency was below 3 MHz. According to everything I know about critical frequencies and MUF (which isn't very much), my NVIS signal from my 17-foot-high dipole should have gone right off into space, and the 70-mile-away station shouldn't have heard a peep out of me (and vice versa).

I'm trying to figure out if the solar storms of the last few days might have something to do with why I was able to contact that station when every indication was I shouldn't have been able to. Sporadic E? I dunno, maybe, but it seems like quite a stretch...

OhMyGosh! Me thinks this will just about be the end of ol' SC! This
will probably kill him dead straight away! Him and about every
General or higher class of log-beaters. . . =)

Actually, this is a radical approach to a troubling issue. Some
times, when pressed, the government just goes too far. This is one.
the "Key" should retain a special place. Again I say it should not be
allowed to "Rule All", but it should have its very own, very special
band width souly reserved to it.

Well, I did a fair amount of moving of receiver and xmitter around the
house, with modest success. My best spot is 35' away, and that's stretching
the limit of the xmitter. However, we now havd DSL after waiting 8 years.
Our den is much closer to the bedroom, and I can use RadioReplay to catch
the station. No interference at all, and I can sent it the short 20' to the
bedroom without much difficulty at all. I say much, because it seems like
the streaming audio runs amuck, and gets distorted somewhat like a too fast
or too slow conversation--alternating. However, most of the time all is
well. I can have the station going all day.

of course i can, rf is a time varying phenomenon by definition. you can't communicate via static fields, by definition, so they are of no use in this discussion.

>You say that you worked in space communication well

no, i don't work in space communications other than occasionally listening to ariss.

>

> I urge you to rethink that one out again.

of course it's true. nec and other existing antenna modelling software is all based on maxwell's equations so by definition it assumes time varying fields and coupling between all the elements of the antenna. if you are trying to do something and ignore that coupling then none of the existing programs will work for you.

>

patents don't have to have significant value, only a new idea, a description of how it may be implemented, and claims. exactly what are you claiming your new idea will do that is unique? you have given a couple examples now of stacking elements, but to what end? is that arrangement supposed to have gain in some direction? is it supposed to be more efficient than existing

antennas somehow? just what is it supposed to do that is worthy of a
patent?

Mr. SC... I agree with your premise that losing the code requirement
will operate to the detriment of ham radio in the long term...
I do not agree with your premise that continuous spamming of multiple
groups with garbage postings did anything except make you feel
important... Good riddance...

denny / k8do

Congrats John you join the club at a unique time where computors are
being used to further the hobby, new horizons that bring challenges
that us old guys never had to deal with. There is nothing like plunging
into unknown brush for miles and miles to come upon a scene that has
never been seen before. Those who take only an easy path will not get
all those scratches and bites that you got on your journey
but you will be the first to get to the top of the mountain before all
the followers and that is the joy of ham radio.
Welcome
Art

then you have nothing new and you should be made aware of the limitations of the software you are using so that you don't get misled any further. unfortunately i don't believe that you have really found anything new, you are probably just ignoring important parts of the solution because you think you can incorrectly apply a static case simplification to a time varying one... sorry, that doesn't work. you may find some examples in certain cases where it looks like it works, but in general it won't.

3973. Re: Critical Frequency and MUF

Newsgroup: rec.radio.amateur.antenna

People are staring to take the computer predictions, simulations and
forecasting too seriously. Atmosphere and ionosphere are very complicated
and are run by Sun and not some wiz programs.
Before the computer models, we used to OBSERVE and LEARN about propagation
from our activities on the bands. Changes with sunspot cycles, time of year,
day etc.
So forget the computer prescriptions and observe and make notes what is
happening when Sub is doing what. One general observation I have found that
with low sunspots in a cycle atmosphere shrinks, angles get lower and
antennas with low angle lobes work better. At High sunspot, atmosphere gets
higher and angles get higher and higher frequencies come to live.
The best, unpredictable and unbehaved band is 160 m, you never know what
happens, just need to be around when IT happens.
Check out http://members.aol.com/ve3bmv/bmvpropagation.htm
on my observations and notes on ducting and refraction.

Awww, c'mon Slow!

To use the vernacular of the left, "It was the Exam, stupid." The mode hasn't changed... hell, it hasn't changed since the 1840's! What needs to change is your attitude about how to entice folks into the Morse Code fold. Since the government stick is gone, you'll have to sell Morse Code on its merits. And here's one last hint, you'll attract more folks if you use sugar. Good Luck.

3979. A request for guidance from chefs

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-16 17:23:02 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <jb98o2pbvqjutfb149l1iecltdiooea8ih@4ax.com>
Source record: 48053

I am presenting a write up on Escoffier arrays
As a recipe which was not directed for any
desirable I laid out the following

All of the elements were mixed in a bowl purely
to make things easier to do plus it being an unusual
arrangement probably never seen before.

Coordinates (perfect ground) Inches
X Y Z

0 209.46 927.1
0 198.25 973.97
0 172.78 822.86
0 219.83 964.4
0 185.53 922.4

With 1" dia elements
my results were
Impedance 48.5 + j 0.1

All elements driven impedances are
6.58 + j56.9
-5.28 - j 37.6
-5.00 -125
9.35 + 58.5
-16.2 - j205

Now, the first request is how did my results find an impedance of
nearly 50 Ohms non-reactive, when every element of my recipe shows
almost 1/5th that value and reactive?

Answer: Voltaics!

Voltas experiments were so long ago that computor wizzords have
forgottne them and they dont now them and dont remember them. But
Votla was a generous compare dto these tyepshe new that when you add
lemon to silver or coper or wrap aluniminium foil around a lemon you
get volts! and voltas is what makes things happen when you squirt the
lemon or lime juise on the elements. this is aslo the reason why we
say put the hjuice to it when we meen add more power!

justhink ofit juice and Volta and voltaix and lemons and uluminium
foil and add salt! Salt is a conductor, because when you add it to
water it becomes the sea and the ocean is the best propagator we now
of.

> wrong way this morning?

The problem is that an "FS" posting in r.r.a.a
violates the netnews guidelines at:

http://www.faqs.org/faqs/radio/personal-intro/

The only appropriate newsgroup for "FS" postings,
according to the guidelines, is:

rec.radio.swap

For sale postings are considered spam by a lot
of the readers of this newsgroup.

The FCC has decided. Let's talk about ANTENNAS and ANTENNA THEORY now.
Now that the decision is final, can we please stop crossposting into
this group?

There are going to be a lot of hams that need advice on HF antennas now
that all Technician operators will have automatic general-level CW
privileges on 80m, 40m, 15m, and 10m. Can we clear out the group so
that they actually think that maybe they can get antenna advice here?

Every ham needs an antenna. I think we can all agree on that.

Welcome to HF everyone!

Dan

I am actually surprised to find out it was/is Vince. He's an O.K. guy, puts in volunteer time and is very knowledgeable. While I firmly believe this alter personality detracted from Amateur radio (Slow Code), Vince has done other things to advance it.

Although I know Vince is very pro Morse code, I am having trouble believing it was him (being Mr. Slow Code)

If it was/is him, turning in his license would only be a detriment to the community IMHO.

yep, thats it. a time varying field makes charges move, so they are no
longer static... that is how coupling works and its a fact of life. maybe
you should try sci.physics.electromag or alt.sci.physics.new-theories, they
are more open to theoretical questions.

>field on a array of static charges

Hi Art,

In point of fact you are the only member of this group to have made that statement. What is being discussed is your inability to come to terms with the simple matter that time varying fields come from dynamic charges which are imposing a force on all charges to react to their change - hence there is nothing static in a field and all charges are coupled. The only thing to measure is the degree of coupling which leads to Q (by a tortuous path of math).

>which is contrary to what I say.

What you say and what you mean is separated by at least one abyss - Gauss did NOT mean static was the noise he heard on his radio while trying to listen to the traffic report.

73's
Richard Clark, KB7QHC

p.s. How do you get 50 Ohms out of 5 wires?
p.p.s. How do you measure Z in a static field?

Brilliant Watson, brilliant!
I pity the fools that were so rong about the antennas and confused the hole scientwific komiunity. Infinite bandwidth, 50 ochms accross, pencil sharp pattern - and we used them mediocre Yagis all this tyme.

p.s. where do you get the antenna mixing bowl?

pspsps It is all now immeterial, you don't kneed to now CW and you don need antennas, it is al replacid by INterNET.

Can I buy me a Extra hunting licens?

Thanks for the link John,

I have been muttering how to use the ocean surface or how to couple to it as an antenna or how to use reduced size, floating on the surface RX antenna for low bands. Jasik makes mention of the phenomena, but I have not seen much on the subject.

C.J. as to the E layer, its effect is probably
next to nil that low in frequency, but, if memory
serves, think that there is a "D" layer, below the
"E" layer, that might have the properties you
speak of? I might have missed some, as I only
download 35 messages at a time, because of all the
junk debates (code-no code, ect). But you raise a
interesting subject as I use on 80, a G5RV, pushed
to its limits (about 15-10 feet off the ground)!
Yet I hear stations that people with higher
antennas cant hear, and it is heard better than
folks with much better antennas than this!
Frankly, this should compare to a wet noodle,
yet consistantly seems to work out to several
hundred miles at night,and on 40 during the day.
The reason it like this is NO TREES in Nevada,
and this property is on bedrock! Not saying this
is an effecient setup , just that it seems to
work! Oh well, sorry for the trouble- thought you
talking about VHF! Jim NN7K

Actually, it's CW/DATA on 10m and phone.

I think it's clever. Techs get giant swaths of CW only privileges
compared to what tech plus before last Friday got.

A little bit of a different perspective if I may.

I am quite hard of hearing. Tinnitus is the main problem. Imagine
trying to copy code with 20 over 9 noise. Haven't experienced silence since
I was 18 y.o. Plus I have several frequency holes in my hearing, estimated
at over 100 db deep.

I studied Morse code for over 6 months, several hours a day. All that
to get to around 7wpm, a level at which a number of code proficient hams
won't even bother to communicate with me.

Flunked Element 1 the first time, a bit of humiliation for a person
who is used to reading something once, then aceing the test.

After passing, I try a bit of CW Morse from time to time, but mostly
do things like PSK and RTTY, which are visual in nature. I can also contest
on SSB and PSK/RTTY, and am very active in Amateur radio, including public
service, and am the chairman of the premier State QSO party in the country.
Not too bad for a person who could barely pass the Morse code test -
according to some, the litmus test of worthyness. Yeah, I'm a nickle extra.
Big deal. I only passed 5 wpm, and you're a jerk.
(those who would determine worthyness in relation to the speed at which
they can swipe a paddle)

I am the poster child for elimination of the Morse code proficiency requirement.

But!

When I first got involved in Ham Radio in 1999, a lot of people told me that I should hold off on the upgrade, because Morse code proficiency was going to go away "soon".

I didn't listen to them, and I'm glad, because all I would have done is cheated myself out of 8 maybe 9 years of the best hobby I've ever found. It was worth all the trouble and more.

So if you have waited for the Morse code testing to go away to upgrade, then congratulations, and welcome to the fraternity, but please accept my sympathy for cheating yourself out of a few years of this incredible hobby.

Finally, if KB7ADL is indeed "Slow Code", I would suggest that you look at your own behavior and decide if it is consistent with the type of people who are in amateur radio who know Morse code well. However nothing is entirely good or bad. The "Slow Code" crosspostings finally got me off the stick to get a newsreader that could filter out the Morse code drivel and the bizzare crosspostings from people with *serious* issues. Thank you!

Morse code testing is dead. Long live Morse CW!

Thanks to everyone for the input.

As it turns out, the problem ended up being something else entirely. I replaced the coax the other evening, and indeed it changed the VSWR. But it still wasn't correct! Ith just moved it on the other side of where I wanted it - what was once minimum SWR at too high a frequency was now at too low a frequency (on 80-75 meters. Then the 40 meter was spot-on, and 20 meters was still off.

Seriously confused, I thought for a few seconds. Why on earth would this weird stuff be happening? Then it hit me. THe OCF is not terribly critical as far as lengths go, but it depends on the height from ground to determine SWR and where that SWR is best. My antenna and support structure was hit pretty hard by the storm we had a couple weeks ago, and probably stretched a bit, and wasnt at the same height as before. (drooped) I suspect that the 40 meter shift, and the 20 meter SWR problem was caused by the drooping ends which didn't get beat up in the storm.

I took it down today, and put up a general purpose dipole running through ladder line and a tuner. Working FB now.

...

There seems a theme in some of the postings that Sporadic E is a VHF phenomena.

Go look at the ionograms from an ionosonde, it can measure the critical frequency (don't know what that means? consult a text book) of the layers above itself at the time, and it discovers E and Es layers. The highest return frequencies indicate the critical frequency, and it isn't (usually) at VHF, it doesn't need to be to facilitate VHF paths.

If the f0Es is say 10MHz, consider the length of the paths, the virtual height of the layer and the MUF for the path (approximated by the secant of angle of incidence * f0Es). If you approximate the earth as flat, a 500km distance to a virtual reflection point at 100km height with f0Es= 10MHz yeilds an angle of incidence of 78deg, sec(78)=5.1, so MUF=51MHz. The earth is not flat, so a slightly longer path is needed for MUF> 50MHz... but the paths commonly worked are 1000 - 3000km, and more. You don't have to do the calcs, some of the space weather sites will fake up an oblique ionogram for you, certainly ours can.

Sporadic E is not the only mechanism in long distance VHF contacts, and contacts are not necessarily dependent on a single mechanism.

But back to the original question, if there is a sporadic E layer overhead at night, why would it not support NVIS 4MHz contacts?

The maps of f0F2 look pretty, but there is reduction of a lot of measurements to a single statistic, interpolation and a delay between measurements and publication that questions their use to prove that the contacts you had could not happen.

I still ask the question "how can they measure f0F2 when there is such strong "reflection" from a sustained E layer that no signal returns from the F layer?".

Owen

Moaning Mark will soon be moaning in ecstacy over the elimination of CW as a licensing requirement, if he is not already.
I welcome the new users to the HF frequencies providing they comport themselves well. The first time I hear an idiot no-coder using an echo box or telling someone, "ten-roger", I am going to speak up.
As for my previous offer to meet Mork on 17 meters? Consider it rescinded.

There is another *plus* to this new rule change in that this will give Woger that many more stations to jam. Tune up your rigs, Wabbit. There is a whole new flock of newbies in the wings who are ripe and ready for your brand of harrassment.

no "not anybody" or is that "Not Everybody" I am pleased it occoured
made a nice hanukah present

30 years ago when it should have done maybe extascy

>I welcome the new users to the HF frequencies providing they comport
>themselves well.

I don't think you will after all you "not anybody
> The first time I hear an idiot no-coder using an echo box
>or telling someone, "ten-roger", I am going to speak up.

how are you going to tell if they are old code tested hams or not

>As for my previous offer to meet Mork on 17 meters? Consider it rescinded.

you never realy made an offer to resind after you have no name and
ntherefore likely no call

>

and here is another place you show true colors as just a general
zenophobe. you like harrassment and encourage it on air and on USENET
this fact about you alone makes ME the better ham

Roy I can kind of see this in a VOR with its rotating antenna but in ILS
systems(glideslopes and localizers) there is no moving antenna. They talk
about AM sidebands being formed due to space modulation.

ok thanks all i over looked the obviious , thought it might have some
use for testing or what ever but if you need 20 to '''get out of the
backyard'''' :) it says it all

thanks

That was a quiver in the force.. I had hit the wrong button and sent
the post by mistake. I deleted it at once, but I guess your server
got it anyway. I didn't actually have any comment on the subject
matter. My cat has mittens when it comes to this "new fangled" miracle
whip antenna theory.

I am installing a Hustler 5-BTV vertical. The Traps all have plugs in the top end and are color coded to the band. orange for 10 meters, red for 15 meters and green for 20m meters, The plugs are made from material that looks like a spong the installion manual says nothung about them. Are they supposed to be removed or not

I never said you did.

> stop lying about being miiss quoted

You ARE misquoting me. Over and over.

> get a life and get help since you are clearly obessed with staking a
> man sexualy

I have a life. It's called employment. You wouldn't know about
that, would you?

And what is "obessed"...?!?! And "staking" a man sexualy"..?!?!

> the truth I trick you in 1998 when you threnting to MURDER me

You can't trick your way out of a paper bag, fatboy, and I never
threatened to murder you.

And further retelling of same is yet another lie.

> stop this whining and face facts you are the one that is sick with
> your obesstion for ####

What's an "obesstion"?

If you meant OBSESSION, then you're talking to yourself since YOU
keep requoting it over and over and using that word blatantly.

> the ruth is you are truly MAD robeson get help

The 'ruth" is...?!?!

I don't know anyone named Ruth in my family.

> and please stop the lie I have seen that you are doing ANYTHING for my
> benifit

You mean your BENEFIT...?!?!

I keep hoping that you'll wake up and realize what a fool you're
making of yourself one day. One can always hope.

> and stop lying about the ToS of Google they expressly prohibit your
> cyvervandalism

What is "cyvervandalism"...?!?!

> and stop lying about my Military service I have my DD 214 as I guess

Hi Jimmie,

I worked on this gear, and more, 30 years ago. Any discussion of
space was physical space. I was involved only with the
instrumentation, but the system specification is characterized in
terms of "signal-in-space." As such, the modulations vary by the
aircraft's position in airspace. This can be in terms of distance,
bearing, slope, or path. In some regions of space, the modulations
change from dash to dash-dot to dots. Shared with these are phase
relationships in both modulation and beam coverage. Testing of these
system parameters is tightly controlled so as to not create
hazardously misleading information to general aviation.

OM,

I'd appreciate any pointers you have to the FAA reference material that defines "Space Modulation". Google shows only links to lists of training courses that the FAA conducts, and references to "Pulse space modulation", which I assume is a different thing.

TIA.

73,

William

Do a GOOGLE search on "Space Modulation" You will find the occasional
pearl among the trash. There is an article about VOR's and Space
Modulation.
What follows is exactly what I understood about the contents: THE, AND, etc.

In other words nothing. HI HI...

I have been looking for a 2-meter yagi, around 10dbi gain or better, that can handle 100 watts for around $100.00.
I was looking at the hy-gain vb-28fm but I do not know anything about this antenna?

Thoughts, suggestions ?

Thanks joe

Nothing like the manual to provide some details:
http://www.hy-gain.com/man/pdf/VB-28FM.pdf

-OR-

Grab some tubing and make one? Industrial recycling yard is cheap
materials. Aluminum irrigation pipe (agricultural outlets a good
source) serves as good construction material, comes in different gauges
for strength.

>FAA reference material that
>defines "Space Modulation"

Hi William,

There is no definition because it isn't part of the argot. The point
of my posting is that the Space of Space Modulation is physical space,
an area or volume in the flight path where all signals are targeted.
This is not about mixing, non-linear or otherwise. It is also not
about modulation waveforms except in how they are intercepted and
recognized by existing equipment (and thus giving rise to HMI,
hazardously misleading information).

It is not that there is anything "in" space that is doing any
modulation. There is nothing inherent "about" space that affects
modulation. Space itself does not modulate. There is no modulation
that requires space to complete it (except in the classic sense of
propagation).

There is VOR space.
There is ILS space.
There is TACAN space.
and on and on and on. Each is overlapping modulation in ostensibly
the same space. Thus we have VOR space Modulation....

Hi Harry,

I used to calibrate these units. Not much service manual to speak of
as the circuitry is fairly straight forward and adjustment is too.

Short of a copy of a manual, any questions I could answer?

I have a VB-214 that was a major disappointment. The eyebolts that secure the elements didn't last two years before they were all quite rusted.

When I tried to buy a replacement set, I couldn't get a firm price (including shipping) from MFJ.

Here is how I fixed it (albeit with a lot of labour): http://www.vk1od.net/VB214/index.htm . From that page:

The lessons learned:

* this Hy-gain antenna had a very short service life because of corrosion of plated steel parts used in its construction;
* replacement parts were not readily available to an Australian buyer;
* it took longer to manufacture the replacement parts to suit the existing antenna than it would have taken to make an antenna of a better design from scratch; and
* critically assess the maintenance issues (eg steel components) of an antenna of this type before purchase.

I don't know if they have changed their construction materials, I won't take the risk on another Hy-Gain.

But a smarter man might either buy a better antenna or build a better antenna, depending on his needs and capability. I bought the VB-214 having just moved and my workshop was 300km away. Today I would build one, but that depends on an individual's capability.

One could build an antenna from the ground up more easily than repairing this one given the difficulty in obtaining spare parts, and use a better boom mounting that either soundly bonds the element to the boom, or easier, reliably insulates the element from the boom.

If Joe is interested in construction, Google around for articles describing element attachment using heat shrink tube and hot melt glue for an insulated element that outperforms poorly bonded elements.

BTW, the gain claims for the VB-214 seem on the high side, I don't know if they are reliable, and the same issue may apply to the 8 element version.

My recollection is that the manual does mention them.

Don't remove them, you will compromise the weatherproofing of the trap.

I don't think any of the regular participants in this newsgroup do reply to the disruptive group. Their messages are cross-posted to many newsgroups, and there seems to be a small group of them who keep each other going, plus I'm sure they raise some responses from rra.policy readers. Each of them seems to feel the need to share their unwelcome banter with inappropriate groups such as this one. What we get here is their QRM, due to their lack of courtesy and adult behavior. I don't see any ready cure for it short of moderating the group. Without moderation, any group of bored children can cause a great deal of disruption, and that's what we have here.

Hopefully, though, the situation is just temporary. As the sun spots improve, 11 meter skip will return, so maybe they'll go back to CB where the level of their conversation is more appropriate and appreciated. I always thought that 75 meter phone was the home for this sort of thing, but maybe they don't have ham licenses.

While over your price range you may want to look at the M2 antennas. They make a 9 element beam on a 14.5 foot boom and a smaller one for somewhat less.

http://www.m2inc.com/index2.html

I put up the 9 element around 65 feet with the ssb set of elements (comes with 2 sets of elements and you use the set for the end of the band you want to use). It may pay to spend a little more for a good antenna that will stay up than to replace one in 5 years. The antenna elements mount through the boom on the plastic insulators. If made out of the same kind as the KLM or Rutlan antennas I have used in the past , they should hold up for a long time.

Also don't forget to use some good coax. I used the Bury-flex type. I just don't like the copper coated aluminum of the LMR 400.

Most likely, truth in everything you covered there Owen. And you are
correct, I have blown much money on antennas, but never had one work
better than those I constructed myself (and this was true even if they
did not work as well! <grin>)

I have had good luck with antenna construction. Ones own work,
attention to detail and use of excellent materials easily defeat those
antennas made with only a profit in mind.

Warmest regards,
JS

Do folded dipoles have better noise rejection than single wire dipoles. I was looking at a drawing one day and realized that they are a dc short. I know loop antennas are very good about noise.

Loop antennas are difficult to install and a folded dipole would be a lot easier.

Thanks Richard
I understand they can be used as an swr meter, reads forward and
reverse. While looking around today, I found the Army version
AN/URM-120 via Sierra also numbered 164B and called a Bi-Directional
Power Meter. The manual is on BAMA I and downloaded it from there,
There are other contractors also, one being Struthers. Thanks for the
offer.

Its my understanding the microvert is the HF equivalent of a "rubber duck"
antenna.

Microvert is certainly no full wave dipole, but for stealth they are
great. Motorhomes, camping, fishing, trailer courts, beaches, parks,
etc.--they attract little attention when disguised in a sun umbrella
(doesn't have to be functional), badminton pole, flag, etc.

You may regret the beam for repeater work. I live in the Greensboro
area and have found that even a tower mounted Ringo brings up too many
machines on a given frequency. Just about any tower mounted antenna
will work into the Mt Mitchell machine and there fore SC!

The real wonder of it all is so many repeaters and so little
activity...

There's some controversy about that but here's my
take. Folded dipoles receive *electromagnetic noise*
just as well (or just as bad) as ordinary dipoles.
However, IMO, there is one type of noise that is not
as bad on folded dipoles as open-ended dipoles and
that is precipitation static noise defined at:

http://www.atis.org/tg2k/_precipitation_static.html

If a charged particle dumps its charge on the floating
wire of an open-ended bare wire dipole, there is only
one discharge path to the other side of the dipole
or to ground and that is through the transceiver.

However, if a charged particle dumps its charge on
one half of a folded dipole, there are two discharge
paths to the other half of the dipole, one through
the transceiver and one through the antenna wire.
The antenna wire discharge path is usually a lower
impedance than the discharge path through the
transceiver and the entire folded dipole is usually
referenced to ground.

In addition, we know that insulated airplane antennas
are less susceptible to precipitation static than
uninsulated airplane antennas. Folded dipoles are
often made out of insulated transmission line.

I guess repeaters in general, whether it GMRS, commercial, or Ham, will still
use CW identifiers, they even use it on satellites.. It seems strange, but it
will be that way for a long time.

Listening to the bands these days I have come to the conclusion that
many Keys have indeed become Silent although they are not physically
dead.

And yes, when more code operators die they are just as dead as any
other amateur radio operator who has passed away.

Three discharge paths --- if the folded dipole is grounded to a boom or mast at the center point of its 'unbroken' side. (As is common with a number of VHF yagis that employ folded (tubing) dipoles as the driven element.)

It's my unscientific, unmeasured observation that my 2M yagi with a folded dipole is bothered less by rain/snow static than my 6M, 'traditional dipole' yagi.

Hello Cecil,

It is not certain that there will be a "discharge" (i.e., a change from a charged state to a neutral one) at all. One possibility is that charges on the wire will simply redistribute themselves after the addition of a new charge. It also depends, obviously, on whether the charged particle is of the same polarity as the preponderance of charges that may already be on the antenna. My pet hypothesis is that these charge redistributions cause changing magnetic fields which appear as noise impulses in the receiver.

Remember from electrostatics that a grounded conductor, such as a tower or an antenna, may not be at ground potential due to induction caused by a cloud of oppositely charged particles, alien space ships, or whatever charge concentration is in the vicinity of the conductor. Even though the conductor is grounded! Of course, when the influence departs, the grounded conductor returns to is neutral status.

Make sense? ;-)

well said indeed althought still maintiain I will an SK only over my
dead body

and Intend for that never to happen even have a plan to carry it out
chinese say "man who finishes house dies" therefore I will never quite
finish my home and live forever

but seriously the attiudes and "proCoders" were one of the biggest
things working in favor of NoCode

Code use is now in the hands it should be in those that suport it .
well on second even I, and I do hate the mode personaly would wish it a
better fate than its supports are likely to contrive but for good or
ill it their problem not mine

but insulting those you are requiting ro seeking to convince was never
a good idea I hope they learn that soon

I heard once it is the sin of the angle times the impedance of a dipole.
Not sure if it is correct but it works for 50 ohms OK. Also heard that if
divide the sine of the angle inot the impedance of a 1/4wl antenna with
ground plane at right angles to the antenna it also works. Again maybe just
for 50 ohms. Might be fun to check out with EZNEC.

What you are looking to do is more effected by antenna hiegth than gain. I live on the NC/SC border and 25 watts into a vertical will get me full quieting into most reapaters within my horizon,. more power or gain doesnt help much. The Mt Mitchell Machine ROCKS. Was involved in a ragchew one night with guys from 7 or 8 different states at least.

I may be using the wrong word. By "discharge", I
didn't mean to imply that it would go to a neutral
state, just that a concentrated charge deposited
at a point on a conductor will be redistributed
over the entire conductor.

I do wonder whether alternatively the noise is not arcing or coronal
discharges caused by the buildup of these high potentials on an antenna.
An insulated antenna would resist charging and if charged, would have
less opportunity to discharge by arcing. The arcing could actually occur
in the receiver.

I have noticed that the precipitation static I sometimes hear sounds
very much like sand/dirt particles striking a glass window in a blow.
Data consistent with either hypothesis, I guess.

Chuck

If you think a DC short will reduce noise, why not just put an RF choke
or moderate value resistor across the feedline conductors of a
conventional dipole?

> Welcome to HF everyone!

One year ago, in Italy the CW exams were completely abolished and our VHF licensees (more of less equivalent to the US Technicians) automatically got the same HF operating priviledges as the full-licence hams.

At that time, there were people predicting disastrous invasions of the HF band by non-experienced hams.

In reality nothing special happened, as just a small percentage of the VHF licensees migrated to the HF band causing no problem at all.

On the other hand this could have been easily predicted:

- a person really interested in operating HF would hardly give up just because of the need to pass an extra exam

- setting up an HF station, especially a good HF station, is not so easy today. Apart from the economic aspect, setting up an antenna that the neighbours can easily note is becoming here a real problem, due to the higher attention that people generally pay to esthetic issues, as well as due to the exagerated concerns on the effects of radio waves on human health.

A bit of a story here but after you read it, maybe someone can make a
suggestion on the best way to approach this.

Currently, I have a 2-m collinear up 52 feet, fed with LMR-600 The rig is
a yaesu ft-2800m at 65 watts.
When I move to Richlands NC. I plan on moving it up to around 80 feet,
maybe higher if $$$ permits.
Right now, I can only get into the 146.820 when the band opens up. maybe
once a week .(I am pretty sure it is in Wilmington but the antenna on that
repeater is somewhere around 1,600 ft, or so they say) but it does cover the
richlands, Jacksonville area.
There is no way that I can get an antenna up high enough (after I move to
the new QTH, to any kind of line-of-site to any of the repeaters here, near
Charleston SC. However, the whitehall repeater is about 500ft and the
greeleyville repeater is up about 900ft.
What would you all do to increase your odds of getting into a reapeater at
that distance?

Just go as high as possible? add a yagi or stack some yagis?

Pray to the DX gods?

Any suggestions?

Thanks joe...

Because that still leaves only one path for the RF
precipitation static, i.e. through the receiver. The RF
is not going to travel through the high impedance of the
RF choke but it will travel through the lower impedance
of the other conductor in a folded dipole or loop if it
exists.

However, an RF choke will eliminate arcing which certainly
does reduce noise.

Unless you are on a high mountain, anything over 100 miles will be very
difficult to work into the Charleston area. . If you do get your antenna
up high enough to work the repeaters over 100 miles away, you will probably
be very unpopular as you will probablay be keying up several other repeaters
, or if they are using subaudio tones it can still cause problems.

What is the distance to the repeaters you will be trying to work?

... and so we come full circle. One either believes in p-noise or one does not. It would be unreasonable for someone who has antennas in an urban environment and some other environments to believe p-noise exists because they will not experience p-noise.

If one were to live where it never rains (or it never snows), one would be disinclined to believe rain (or snow) exists. Many years ago (no, I am sure I have not told this story before) I was asked by a colleague who lived in a country south of Miami to tell him about snow. Well, I said, it is a bit like granisado (flavored, shaved ice) without the flavoring (do not eat the yellow snow) and heaped up everywhere. He was too polite to indicate his disbelief.

So, what is your religion?

Warm and fond regards, Mac N8TT

It never snows around here, but no one disbelieves in snow, Mac.
Cecil's idea of the nature of precipitation static is pretty much
based on what he's made up in his head, and not on measurement and
experimentation. Moreover, he puts words in the mouths of people
who disagree with him, such as the above: if you disagree with him
he'll say you don't _believe_ in p-static, as if it were part of some
ham religion. Actually, it's Cecil's ratiocinations that aren't worth
"believing in." Anyone, even you, can investigate the phenomenon of
p-static with some simple homemade equipment, as I referenced in an
earlier post. Then you can decide for yourself how likely it is that
Cecil's ideas have merit or not.
73,
Tom Donaly, KA6RUH

I saw P-static today on the spectrum scope of my
IC-756PRO. I bought a new backup battery and am
allowing it to power my transceiver to see how
long it will last. I tuned it to 1620, WTAW, in
College Station, TX. The typical AM pattern showed
up on the scope. The display has a memory mode where
past signals are remembered in blue while present
signals are displayed in green. It started raining
and after awhile, I went to check on my transceiver.
The display was back to normal as far as the green
display but the blue memory display was constant at
5 divisions completely across the 50 kHz covered by
the display. The carrier was only one division higher
than that blanket of noise caused by the rain. This
was 10 dB per division. I heard no thunder today.

This evidence should be repeatable for anyone with
a spectrum scope on their transceiver.

They are not my ideas, Tom. Simply do a web search
for precipitation static. There are hundreds of
references including the following definition by
ATIS, accredited by the American National Standards
Institute (ANSI). Check it out for yourself.

http://www.atis.org/tg2k/_precipitation_static.html

WOW
Thank you all for the information. I found some very positive reports about folded dipoles. I will try one this spring. I live in the North Country and it would be quite hazardous to try and hang one in all the snow and ice.

I have seen these dipoles already constructed and made up for sale. I guess I will just have it all ready when the thaw hits. I will try to find one with a current balun.

Michael

Maybe. Arctic National Wildlife Refuge. I've never seen it, don't want to. No one I know has ever seen it. No one I know wants to see it. But you can go see it if you want.

Michael, please do not spend good money for something you can build yourself for a fraction of the cost, and learn good things in the process...
An 8X10 piece of plexiglass storm window from the hardware store will supply strips for the end and center insulators... A chunk of 300 ohm TV twin lead will supply the folded dipole material... A roll of coax, some solder, and a pieces of small rope, and you are in business... A hack saw will cut the plexi (so will a skill saw or table saw)...
Why not make one for 10 meters as a starter until spring comes... This can be hung between two trees <or whatever> so it is at least head high and will give you some fun when the band opens here and there..... You can check the formula for length versus resonant frequency...

Then you also need a short across the other side of the folden dipole
or loop (the feedpoint) and then all of those pesky noise problems are
completely solved. If you add a 10 dB attenuator between there and the
input to the transmission line then you will also have a nearly flat
SWR too.

A nearly perfect antenna. Completely flat SWR, totally noise free and
with equal gain in all directions! What more could you ask for?

:-) How about some functionality?

Let's take a look at a G5RV that I bought when I moved
to AZ and got back into HF operation. One side of the
G5RV dipole was DC floating at the antenna tuner output
while the other side was DC grounded. During AZ desert
windstorms, this new G5RV of mine arced at the coax
connector due to precipitation static, sometimes several
times per second. Putting up a 40m folded dipole caused
the arcing to cease. Seems to me, an antenna that doesn't
arc is more functional and less noisy than an antenna
that does arc. :-) In addition, even when the wind was
not strong enough to cause arcing, the folded dipole
delivered less noise to the receiver than did the G5RV.

Folding and insulating are two methods of reducing
precipitation static in airplane antennas. The G5RV
was not folded - the folded dipole was. The G5RV was
not insulated - the folded dipole was.

Hmm. I've lived in AZ for over 60 years (almost 50 of them as a ham)
and am well familiar with dust storms and static build up on antennas
but I've never heard of it being called precipitation static.

Whatever you choose to call it, Roy's suggested rf choke would have
solved your problem.

>In the thread Rain static I referred to a closed surface which is
>clearly
>defined by Gauss's law.

Hi Art,

A "closed" surface is described by its geometry, not Gauss's law. No charges, Gaussian or otherwise, are required to "close" it. Rather, what is defined by the "closed surface" is the charge. You measure the charge by moving it through the surface. I will explain below how this too is wrong.

>If the surface is an
>insulator type then it takes a long while to penetrate

A closed surface is not required to be of any substance to still be a closed surface. Closing the surface is simply a mathematical description of space, not what is within it.

>but if the
>surface
>is a good conductor then the charges will penetrate very quickly

Now, if we were to consider a material that is bounded by an equation (like a cycloid, or volume of revolution); then your two examples are described BACKWARDS. Charge on a practical, conducting surface will NOT penetrate to the inside because the mutual repulsion forces charge to the point of least curvature (this is why spark gaps using sharp pins have a lower breakdown than those using balls).

Another concept you have wrong is the nature of current and flux. Flux is a vector of charge, not the movement of charge. Flux and closed surfaces are used to prove if the charge is inside the surface (the flux transits an odd number of surfaces) or outside the surface (the flux transits an even number of surfaces).

Hence, the remainder of your discussion doesn't make much sense, does it?

Hi Art,

Hence, you stand to learn from teaching - n'est pas?

Your having nothing substantive to respond to in terms of the topic,
it stands to reason you cannot reject my coverage which is in fact
elementary Coulomb and Gauss.

You still have not broached the subject of how you accumulated 50 Ohms
non-reactive from 5 wires haphazardly strewn about, nor explained how
you measured their Z in a static field. We await something of more
technical deliberation from you.

4099. Propagation Characteristics Of the 60 Meter Band ??

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-19 17:07:48 UTC
From: Caveat Lector <CL@nowhere.com>
Message-ID: <B%Uhh.25578$6J4.17997@newsfe08.phx>
Source record: 47873

I need to write up a brief description of the propagation characteristics of this band.
Being it is between the 40 Meter and 80 meter band, I assume the 60 meter band is local or very poor during the day. At night in the winter months, propagation should offer characteristics similar to the 40 meter and 80 meter bands. Have read some reports of NVIS being used successfully for local day communications.

Given that few countries (United States, United Kingdom, Norway and Iceland) have privileges here and considering the power restrictions --- (Amateurs may use USB *only* with a maximum effective radiated power (ERP) of 50 W. Radiated power must not exceed the equivalent of 50 W PEP transmitter output power into an antenna with a gain of 0 dBd), it would seem domestic contacts (USA) are most likely.

Any comments are appreciated. Post here is fine.
I remain incognito on the NG's due to bad experiences in the past.
TIA

Any idea what causes my Yaesu G-1000 rotor control box to chatter or
buzz after the rotor comes to a stop? This happens if it is rotated
to a position using the automatic feature (where you set a position
and hit a button and the rotor goes there and stops).
It's as if the rotor might be moving back and forth at a high rate,
and the controller is trying to correct for it.

Thanks for the suggestion. I have decided to make my own. There are suggestions on the web that radio shack makes some good twin lead. However, I still would like to put up a balun. What would be the best balun for me? I intend to operate on 75 meters.

I admit to being a ham since 1956. However, I have not been very active and now that I am retired would like to get on low band. I am not very knowledgeable on all the types of antennas. I do know how to make a random wire work but do not want that type of antenna again.

Also, to keep the twin lead insulated, do I need to coat the ends where they are shorted?

I do appreciate the successful reports of using this type of antenna. What might happen if I put an antenna tuner on the transmitter end and tried to operate a folded dipole for 75 meters on 40 meters?

I cannot safely use my trees until they are thawed. I cannot climb them myself and I would not pay someone to do this until it is safer.

Michael

> times per second.

Hi Cecil -
Just a small bit of elaboration on your point - the arc is the result of the accumulation of a sufficient amount of charge to facilitate an electrical discharge in air. Static is heard in the receiver as the charge is being acquired, but an AGC limited pop would be heard when an arc occurs. (And sometimes nothing at all after the latter :-)

> Putting up a 40m folded dipole caused
> the arcing to cease.

That's right. The accumulated electrostatic charge would be distributed uniformly along the length of such an antenna. Both ends of the antenna would therefore be at the same potential, so there is no propensity to arc across them. If at least one of the antenna terminals on the rig is grounded, the likelihood that the antenna will accumulate a significant amount of charge is greatly reduced. The antenna is still just as likely to produce precipitation static noise however. If the receiver input was strictly differential, then it would indeed be completely insensitive to common mode signals and noise.

Reports of the death of Morse Code are, of course, premature. This
morning at 7.30am there were plenty of CW transmissions on 40 & 80m.
But there again I am in Europe.

Charlie.

As frequency decreases wavelength increases, Cutoff is the longest
wavelength that will fit in the pipe.
Fcutoff = speed of light/2 times the largest crosssectional dimension of the
waveguide

or Fc= C/2d

However the wavlength of a frequency in free space is significanty
shorter than the wavelength inside the waveguide so the actual Fc will
be greater than that calculated usng freespace values. My slide rule says
that if the angle of incidence inside the waveguide is 45 degrees and the
free space wavelenghth is .05 meters wavelength inside the waveguide is
about .075 meters. Dont hold me to these numbers but they should be
reasonably close. Im not very good at writting equations using a computer
but the Practical Antenna Handbook by Joeseph Carr has a pretty good
discription of whats going on. I am sure others will give you more
references and probably more precise numbers.

> defined by Gauss's law.

Gauss's law doesn't define a surface, the surface is any arbitrary surface
surrounding a charge.

>Let us now look at a time vary field applied to
>
> a dielectric. I fht efield is applied for the shortest of time the
> charges
> will stay on the surface. If time is longer than the shortest space of
> time

you make it sound like there is some 'shortest' time where charges won't
move. this is not true. no matter how short you make the time it will move
the charges.

> then charges will openetrate the closed surface. If the surface is an
> insulator type then it takes a long while to penetrate but if the
> surface

Here you mix up 'surface' and 'surface'. the gauss's law 'surface' is a
mathematically useful construction around a charge, it does not have any
charge 'on' it, nor is there any 'penetration' of it by charge in gauss's
law. it is strictly a non-material thing that is used only for calculation
purposes.

> is a good conductor then the charges will penetrate very quickly so
> we can associate the time constant of penetration to the subject of
> skin depth. If we are to associate the time varying field to a
> gaussian field

you have yet to define a 'gaussian field'. gauss's law applies to electric
fields and their relation to charges.

> all the excess charges must be on the surface by law.

only in a 'perfect' conductor. dielectrics and 'empty' space can have
distributed charges throughout.

>Or in other words
> the time evolved must be shorter than the time required to begin
> penetration.

huh? it just goes down hill from here. write some equations, do some drawings, publish a manuscript. all the rest is empty handwaving based on incorrect assumptions and missing definitions.

if its only when using the preset feature then its likely the circuit that
nulls the voltage difference between the pot in the rotor and the preset pot
in the control box. just press the rocker switch and it should stop.

If I press the off switch it stops it also (naturally !). And when I power back on the problem is
gone, until I go to a new antenna position with the preset function. I tried your suggestion and it worked. So it is now just a bit annoying in that I have to wait till the antenna gets to the preset position automatically, and then reach up and hit the switch. Ok, I will live with that. Thanks Dave

think of it as an alarm that lets you know the antenna is in position and
ready to use!

i haven't been in to that part of their control circuit, and since they
don't label stuff very well on the schematic i would only be guessing... but
the first thing i would check is that you have good connections on the
indicator pins of the cabling. and check for leakage from the indicator pot
to ground that could indicate water in a connector or cable. either of
those may upset the balance of the nulling circuit they use.

AMEN!!!!!

"It's all been seen before" is just bunkum. My PSK31 cables are new to me. My EME dish is new to me.

Fortunately, nobody gets a lock on first-time discoveries in this hobby. My pulling a QSO out of the noise today is just as much a thrill for me as it is for another half-million or so hams when they do it.

I'm working on my first HF antenna. Hand-built for 10M, it will be -- and on the air as soon as I'm legal.

Speaking of legal, when I'm doing low-power antenna tests for matching,
what's the protocol for ID'ing? My antenna experience is limited to FM,
where I easily ID through the mike with one hand while twiddling the SWR
meter with the other.

However, if I steady-key on HF to measure VSWR, I obviously can't ID; if I
use voice, the needle's bouncing.

Does the HF community tolerate occasional non-ID'ed transmissions for
essential testing????

as I recall the rules do permit short oneway tramission ofor the
prupose of testing Not sure the exact wording right now

although for a lowpower tuning signal the could id prehaps RTTY would
as it is all but a stable source of power output at least wrt to speed
of swr metter might do

Today I was making some measurements with my MFJ-259B. From the manual, I read:

"The MFJ-259B measures reactance, and converts reactance to capacitance. The MFJ-259B
can not determine if the reactance is actually inductive or capacitive. You can usually determine
the type of reactance by adjusting frequency. If frequency is increased and reactance (X on the
display or Impedance on the meter) decreases, the load is capacitive at the measurement
frequency. If frequency is reduced and reactance decreases, the load is inductive at the
measurement frequency."

Then I looked over the measurements that I plotted out. If I look at the graph of the reactance, the amplitude of the reactance will increase and then begin to decrease as frequency increases. If I try to follow the tip given in the MFJ manual, the reactance can appear as both capactive and reactive before it ever crosses zero. For instance if I follow the graph it rises and then starts to fall - according to the manual this would mean the upside is inductive and the downside is capacitive. But what I don't understand is how that is possible - it seems to me it would have to cross the integer value zero (0) to change from capacitive reactance to inductive reactance?

What concept am I screwing up here?

-Scott, WU2X

Here are the values I measured:

Freq	R	X	SWR
144	44	2	1.1
144.25	46	4	1.1
144.5	55	7	1.1
144.75	60	7	1.2
145	68	0	1.3
145.25	78	0	1.4
145.5	79	0	1.4
145.75	73	11	1.5
146	63	21	1.5
146.25	53	23	1.5
146.5	46	21	1.5
146.75	40	18	1.5

```
147 37 10 1.5
147.25 35 8 1.4
147.5 37 6 1.3
147.75 41 10 1.3
148 48 15 1.3
148.25 59 19 1.4
148.5 75 16 1.6
148.75 90 0 1.7
149 96 6 1.9
```

I didn't mean CW was "gone" in the sense of no longer able to be used! I meant only in the "testing" - which has spawned months if not years of hateful arguments - so it is pointless to remain at odds with others over it. Sure - CW, AM, RTTY, etc - are still all there to be used and enjoyed by those with personal preference. And as well - they should be! Use them to your hearts content!

Has anybody experienced this first hand? I was driving during a storm listening to talk radio and could distinctly hear a static rush build up from the radio 1 to 2 seconds before a lighting strike. The louder it was, the closer the strike was going to be.

A little off topic. I know this was not antenna static build up, but found it interesting that you could listen to a charge building before a discharge.

Hi Scott, It probably means you are measuring the impedance through a length of lossy coax. If you do the sweep using an electrical 1/2 wavelength of coax at say 146 MHZ you will probably see more of what you would expect. I think the MFJ manual gives instructions for cutting a 1/2 wave xmission line. If you have EZNEC you could do an SWR sweep of your particular antenna and see what the impedances should be. Then take the MFJ readings right at the antenna or through a multiple of 1/2 wave coax. The results should pretty closely agree.

If you still have problems, then there may be some strong RF present that is disturbing the measurments, or YOUR presense in the near field of the antenna could be upsetting things. If you are trying to measure

a voltage fed antenna like a J pole, if you are physically close to the antenna it will foul things up. Good Luck.

Looks like coax to me too....

Another problem is that the MFJ-259 isn't a very good VHF impedance meter. The resistance and reactance readings aren't going to be at all reliable on 2m, unless the impedance is close to 50 ohms, resistive.

I recently recalibrated mine since it was giving weird results on purely reactive loads. The calibration procedure checks resistive loads of 12.5, 50, 75, 100, and 200 ohms. I used SMT resistors on BNC connectors as decent loads.

After I did the calibration, the 200 ohm load at 144MHz reads something like R=80 X=50!

In the VHF range, even a good N-connectorized 50 ohm termination shows a little tiny bit of reactance. R=49, X=7 or something like that.

>From 1.7-30 MHz my 200 ohm load reads R=200, X=0. Up to about 60 MHz, a little "reactance" creeps in, some of which may be genuine (connectors and adapters), but much of which is simply due to the bridge being substantially off up there.

If you want to do experiments with the '259's capabilities and plot resistance and reactance curves, work on HF instead...

That said, if you're doing this through coax, try it again without and your results might make more sense... you are "close" to 50 ohms resistive...

It's not a matter of what we tolerate. It is a matter of FCC rules. Even a
test transmission (including tune-up) must conclude with an ID. So you
tune, then ID.

I have heard it to the point where the radio was desensed
just before the lightning strike. This happened with AM
radio in a fringe area.

Here's some information on the subject. The electrons that
discharge into the earth during a thunderstorm return to
the atmosphere as fair weather current.

I don't give a damn what they call it, here's a definition of
precipitation:

precipitation n. a: a deposit on the earth of hail, mist, rain, sleet
or snow: also: the quantity of water deposited.

I don't see anything about dirt.

I am in W1-land.

My antenna is a 150 feet long CF doublet using tuned feeders.

My log shows:

1] daytime, 9:00 am through 3:00 pm ... up to 300 miles
2] sunrise/sunset up to daytime ... up to 1000 miles
3] dark ... up to 3000 miles [I have G1 confirmed], also St. Lucia in the Caribbean.

Running 40 watts ERP.

You could attach a weight to a piece of rope or cord, throw it over a
limb, and then hoist the end of the antenna up. Beats climbing, ice or
not, and to adjust the antenna, you just loosen the rope, and let the
antenna down.

As you know, words often have a different technical
meaning than their common Webster's dictionary meaning.
The adjective "precipitation" modifying "static" or
"noise" has been extended to dust as well as rain or
snow, just as the p-static definition indicates.

Airplanes flying through rain, snow, and dust exhibit
the same physical phenomena so dust has been included
as one of the causes of precipitation static. A web
search will prove that to be true. Example quotes:

****

Volume 2, Issue 4 (December 1945)
Journal of the Atmospheric Sciences

Article: pp. 205ï¿½213 | PDF (801K)
METEOROLOGICAL ASPECTS OF PRECIPITATION STATIC

Robert C. Edwards, Lieutenant U.S.N.R. and George W. Brock,
Captain U. S. A. A. F.

ABSTRACT

Precipitation static, a result of electrification of aircraft
in flight, can cause loss of radio communication for long periods
of time. Electrification may consist of either of two types,
ï¿½autogenousï¿½ or ï¿½exogenousï¿½ electrification; autogenous electrification
occurs when snow, *dust* or rain strike the surface of the aircraft,
while exogenous electrification results from an aircraft being placed in
a pre-existing atmospheric electric field. Serious autogenous
electrification occurs only in snow and *dust* storms; ...

****

Please note the date. Precipitation static from dust has been
recognized for more than half a century. There are many more
references available. One advertisement asks the following

question:

From FCC Part 97

(b) In addition to one-way transmissions specifically authorized elsewhere in this Part, an amateur station may transmit the following types of one-way communications:

(1) Brief transmissions necessary to make adjustments to the station;
97.119 Station identification.
(a) Each amateur station, except a space station or telecommand station, must transmit its assigned call sign on its transmitting channel at the end of each communication, and at least every ten minutes during a communication, for the purpose of clearly making the source of the transmissions from the station known to those receiving the transmissions.

So you have 10 minutes before u need ID

True, but it was a little wide.

OTOH some power companies run great spark transmitters.

Hello Laura,

Regarding your rectangular wave guide question:

Mostly a waveguide for energy transport is not used close to the cut-off frequencies. If you do, the losses of the guide will be high. At the cut-off frequency (and below for H10 mode), the wave vanishes exponentially of a short distance.

To reduce the losses, you should choose the operation frequency well above the cut-off frequency of the propagation mode that you want to use. Minimal loss is obtained around twice the cut-off frequency for H10 mode (H10 mode, H-field has component in direction of propagation, E-field has not, there is one E-field maximum along the largest width of the guide).

Many modes of propagation can exist, especially when the operating frequency is far above the lowest cut-off frequency and other geometry is used. The way of excitation (for example coax to waveguide converter), together with the waveguide dimensions determine the "dominant" propagation mode.

Besides the waveguide loss, there is also a group velocity. Close to the cut-off frequency, the group velocity changes strongly with frequency. This introduces envelope distortion of the propagated signal (if you were using AM). Of course this only counts for very wide band signals.

Best Regards,
Wim

I thought the SWR curve looked strange as well. The SWR has a weird
curve across the entire band. The antenna is actually a 4 element quad.
Its fed with a W2DU style VHF 1:1 balun. The coax is a short run of
RG-8X. The RG-8X uses PL-259s on both ends and I soldered a SO-239 onto
the coax for the balun (see pictures). Any issue with using PL259s and
a SO239?

Here is a picture of the feed system:
http://www.wu2x.com:8888/usenet/P1010062.JPG

Here is a picture of the antenna under test:
http://www.wu2x.com:8888/usenet/P1010058.JPG

This is the data graphed out, so its easier to see:
http://www.wu2x.com/usenet/ReadingA-ReadingB.htm

I took measurements with it fed for vertical polarization and
horizontal polarization. The results are both shown on the graphs.

This is true, but I always begin and end a tuning or test transmission
with "N3OX TESTING" in fast CW.

It will make those who hear your 1W loud and clear happier. They'll
know someone is running tests instead of just sitting on their key.

Your coax is what, 10-12 feet long? That's pushing a couple of wavelengths on 2m, but isn't quite there.

To read the impedance of the antenna directly and get a good set of resistance and reactance curves clearly, you need probably less than a foot of coax, or an exact multiple of an electrical half wavelength (so exactly 2 wavelengths * velocity factor would do it). You can use your MFJ-259 to cut the line.

It's possible to transform your impedance readings into the antenna's impedance if you know the (random) electrical length and loss of the coax and are handy with a Smith chart or have some other calculating ability.

Exact multiple of a half wave is easier... it's an impedance repeater, aside from the loss in the line. To that end, I'd use an exact multiple of half wave of better coax... RG-8 or 9913 or something.

73,
Dan

4146. Re: Crankup Antenna as Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-20 17:51:16 UTC
From: Bob Dixon <dixon.8@osu.edu>
Message-ID: <dixon.8-F7816D.12511620122006@charm.magnus.acs.ohio-state.edu>
Source record: 47820

I have successfully done exactly what you propose. I have one crankup
tower that works on 80 and another that works on 160. Both benefit from
HF and VHF antennas on the top for top loading.

There was an article about this some years ago, I think in CQ.

The main trick is to operate the tower as a reverse ground plane.
At the highest point on the tower which does not move, attach the ground
side of the coax to the tower (bare metal). Also install 4
quarter-wavelength insulated horizontal radials from that point to
remote points, such as trees etc. Connect all the radials and the
center conductor of the coax together.
Then run the tower up and down and tune for minimum swr. My larger
tower with several HF beams on it tunes fine on 160. My smaller tower
with VHF beams on it tunes fine on 80. The last time I used it, I worked
Morocco on 75 SSB in the late afternoon.

As the tower moves, the connection is not perfect, so the SWR jumps
around a little. But once the tower stops moving, the connection is
solid and works fine.

Hi Scott,

Well, I can plainly see the BalUn in the first picture. To be completely decoupled a second one a quarterwave away on the feedline would help, but the numbers look far more whacked out than that might cure (because it probably isn't the problem to cure).

>The coax is a short run of

I notice from the picture you don't seal anything. Those connectors are leakier than a sieve.

Aside from these comments, perhaps you should validate your meter by measuring known loads. It sounds simple, but in the VHF it is not. Common garden variety components like resistors and capacitors have values that diverge greatly from their markings. So, some care in their selection (or construction) is warranted.

Anyway, grabbing components out of your junk-box would serve as a first pass attempt, but it shouldn't end there.

Its not that I am trying to get the exact feedpoint impedance values
from the antenna. I understand how 50 Ohm coax affects the values that
I've measured. I was originally trying understand how to determine if a
reactance
value was capacitive or inductive.

I do see now that when I use NEC2 to plot the values for this antenna,
the resistance and reactance appear more linear across the frequency
range I measured. I see if I apply the logic of the MFJ manual to the
plot from NEC2, it makes sense and that my data is all over the place.
For what reasons I do not know. I do not think the feedline is
radiating. Maybe it is just the meter. Or perhaps some larger deviation
from 50 ohms in the coax and connectors.

And Richard - the antenna doesn't stay outside, that is why its not
sealed. This is just rigged up for testing.

I tried using one of those MFJ analyzers on 2M and it didnt work so great.
One of the big problems wa that my presence would effect the reading. I
could see the reading changed as I walked toward the antenna. I had the same
problem with cable length. An SWR meter became more valuable.

I never actually said 10 -12 feet. My coax is 20 feet long. My
movement doesn't change the values at all. These values aren't erratic
either. You can move the coax around on the boom and mast and it
doesn't make the slightest difference on the readings.

Oh well, maybe I'll have to move my prototyping to the 6 meter band.

Looks like you have a double dip in impedance typical for staggered tuned antenna. Is one of the elements "pulling" it or maybe effect of the other balun and coax within the antenna? (It is in the same plane as the feed and might be resonant causing the "other" dip. Something like OWA Yagi.) Try to remove it or check the element dimensions.

Made one using EMT conduit.
Did a 20M vertcal endfed with a stub made of ladder line. Works as expected.

If I were doing it again I would make it 5/8ths. IMO the 5/8 would be easier
to tune up.

Sorry if I gave that impression. I simply meant that a folded dipole is just as likely to produce precipitation static noise as a dipole antenna.

Hi Jim,

Can you elaborate further on your understanding of just how an
ungrounded antenna wire that receives an increment of charge causes a
response in the receiver as the charge is being acquired?

If dust particles are charged as raindrops are (mixed polarity and
magnitude) a typical incremental charge is on the order of 8
picocoulomb. Do we have an understanding of how much power would be
transmitted to the 50 ohm input impedance of the receiver by such an
incremental charge and the mechanism by which that transmission takes
place? Based on anecdotal info, it is not unusual for these impulses to
appear at an average level of several S-units.

Thanks for any insights you can share.

>
> What concept am I screwing up here?

Scott, your measurments are all over the place like a wild woman's
whatchamacallits.

Is the broadband detector in the MFJ being influeced by RFenergy received
by the antenna? That will make the readings worthless. Just try a quality
reflectometer (eg a Bird 43) and see if the readings are consistent with
the '259... if they aren't ask yourself why.

My experience (like others reported in the thread) is the MFJ259B is
potentially misleading on 2m.

As for your original question, MFJ's hint is useful, but visualise where
your observations mapped on a Smith chart, and assumption of one of the
two possible signs for the reactance will often seem less sensible or
even inconsistent. Additionally, it you calculate the load impedance
(considering the line's characteristics) at the load end of the line, and
consider readings at several nearby readings, again one of the two
possible sign assumptions for reactance will seem less likely to be true.

(Pity you can't plug in a line type and length and the analyser calculate
the impedance at the load end of the line, may be do it now? The
calculator at http://www.vk1od.net/tl/tllc.php will perform the calcs for
you.)

I see advice that you use an integral electrical half waves of coax or
just a foot of coax. Neither eliminates impedance transformation by the
coax when you sweep 4MHz as you have done.

Hi Chuck - given a large enough increment of charge it's pretty straightforward. Best example I can think of is a capacitor. Take a high gain amplifier with an input coupling capacitor and start daubing clumps of charge onto the unconnected input lead. When the amount of charge is big enough, you'll hear the pop that results from the instantaneous change in charge. Thousands of those per second and pretty soon we're talking some real noise. ;-)

I've never worked these numbers before, but given your typical charge per particle of 8 picocoulombs, and a 16uV signal from a 50 ohm antenna (converted to uamps), I get about 4x10^4 of those particles per second. Given the density of air, that's a pretty low number I think. If I'm wrong, please don't blast me. The back of my envelope here is pretty messy and hard to read. :-)

The closest thing to this I came across is Hertzian dipole fields via looking at static/quasi-static waves.

Quick summary below without reproducing lots of formulas:
The hertzian dipole is 2 charges +q and -q connected together by wire. q= I/w sin wt. -q= -I/w sin wt.The formulas are then followed through and solved to obtain 1/r terms which are in phase. Obtain power crossing a closed surface. Poynting vector must have a 1/r squared term, and formulas for E and H must have 1/r terms and be in phase. The formulas for E and H fields then satisy Maxwells equations. The formulas obtained via the quasi-static fields route are the same as those obtained via the magnetic vector potential route.

Yes, once you throw in the (sometimes negligible, sometimes significant)
complications that real "ground planes" are finite in extent and have non-zero
loss.

> What about fibre optic cable? If ordinary glass strands were used, when the
> cable was bent, the light would be blocked and not travel any further.

Fiber optics aren't antennas; fiber optic "cables" are low loss (ideally
lossless) dielectrics clad in another dielectric with a different enough
permittivity to create total internal reflection. Using traditional
terminology, fiber optics are actually just a particular type of waveguide.

Gary, I wonder if you have a second language? If you did you would
understand.

Yes, the question is rough English, but I could understand the IT.

I suggest you get off your high horse and make as much effort in
trying to understand the posting as the poster did in trying to post
it.

Thinking in another language, especially in later years, is very
difficult. If you haven't done it then I suggest you not criticize.

You shouldn't doubt a chart of things that happened. What you said makes sense, otherwise. As Cecil said, the radiation leaves your antenna at (optimum) angles between 9 and 53 degrees. (That's the half-power beamwidth in an elevation view.)

Low angle radiation, the ground wave, peters out after a few miles, but you do get local contacts with it. High angle radiation goes into space and is lost. The mid-angles are refracted in the ionospere and returned to earth. That's your set of distance range contacts.

Think of how it would be to toss a tennis ball toward a ceiling: If the ball could go straight up through the ceiling, it would be lost; also, if a low-angle toss never hit the ceiling, it would also be lost. It's those mid-length tosses that bring the ball down somewhere in the room that pay off. I realize this is an imperfect metaphor, but it may do the trick for you.

I dont doubt waht Cecil said but the way this chart is written it would make
you think that you should base the angle of radiation on the closest
contacts that are "skip". I assumed that someone COULD make a chart like
this. I was actually hoping this would be the case because it is much easier
to discern that leading edge than try to pick out some point in the middle.

NOW I dont this this graph wa intended to be used to determine the radiation angle of any particular antenna. Rather I believe now that it was intended as an educational tool to get across the relationship between vertical angle and skip zones.

Here we go again.....
Simple question, understandable, flame, more flames.

Hey, Merry Christmas to you guys.

The answer to the original question is, there are a few (at least 3 I know of).
EZNEC is a favorite of many on this newsgroup and can be tried out for free.
4NEC2 is another. There is a list of some at this link:
http://www.dxzone.com/catalog/Software/Antenna_analysis/
If you do a google search of "NEC4 antenna model" or similar you will get more than you can handle.

Myself, I have used 4NEC2 and getting somewhat familiar with it. Once I researched the concept of "cards" it suddenly made sense to me.
I believe these NEC2 programs use the same "engine" meaning when your front end program generates the data, it is fed to the same calculating software, regardless of the program. So the main difference in the programs is how convenient they make it for you to enter your data, the display of the results, and of course the support you get to go along with it. In that category I have heard nothing but praise for W7EL, Roy, who participates on this newsgroup and has been involved with modeling software for a very long time.

There is also an email reflector on the subject. I don't have the info handy right now but I am sure you can find it (as well as anything else in the universe) with a google search. Read the archives there and you will find tons of info and supportive help. This newsgroup is a little tough, because the subjects range all over the place, and there are so many guys who have their rifles loaded and just looking for someone to make a false move.

Tell you what I'm going to do. I will post another article following this one and give you some idea of what I expereinced with my first attempt at modeling. This may give you some ideas of what to expect.

Source record: 47703

Jim Kelley wrote:
> I simply meant that a folded dipole
> is just as likely to produce precipitation static noise as a dipole
> antenna.

Probably not true for a bare-wire dipole Vs a ladder-line folded dipole. Insulation is one well accepted method of reducing precipitation static on airplane antennas. In any case, the two wires in the folded dipole make it different from the single wire in the dipole.

I'm away from my computer for the moment but consider your capacitor suggestion. Let's say we have a perfect ground plane and are testing a dipole Vs a folded dipole. They are in inverted-V configurations so we can discharge a capacitor between the end of the antenna and ground. For the dipole, there is only one path to ground through the receiver. For the folded dipole, there are two paths to ground, one through the receiver and one to ground. Why won't the charge applied to the folded dipole divide and take both paths?

4180. Modeling, beginners luck

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-21 13:49:48 UTC
From: ricknj10@hotmail.com
Message-ID: <458a8937.145164953@news.optonline.net>
Source record: 47704

I am changing the subject slightly hoping to avaid the flaming that has started.

I will briefly sumamrize some things I learned from my experiences with 4NEC2. Maybe this will inspire. Remember I am a beginner.

First of all I modeled my rhombic antenna I was building. I used an inputting method called geometry edit. This is fairly easy way to input the dimensions of the wires of the antenna and gave valid output. But I found it cumbersome to change the dimensions. In fact I had to do some trig to figure out the X,Y coordinates of the changed antenna. But it DID work, and I found out a lot about modeling and the rhombic, but I could not get the "optimizing" feature to work. It kept telling me I had no variables to change. So I did some reading in the generic NEC2 documentation and learned about "cards." And then I studied some examples and learned how to input data with the NEC editor. With this method, you define variables such as the angle between the legs of the rhombic, and you only need to do it once. Then you can have the program change the variable for you and output the data. For example you could include a variable for the terminating resistor, have the program change the value of it while checking for forward gain. Or you could change the lengths of the wires easily or the angle, or make one wire longer than another, anything you want. Also can do a frequency sweep to see where your antenna is resonant.

So I will close with two things I have discovered through my experimenting with the program and with getting out in the woods and putting up wires. The first is that I believe the model accurately determined the characteristics of my rhombic. It showed I could expect about 13 dbi gain, about 22 db f/b and a 20 degree beamwidth, at a height of about 30 ft. It also showed about 12 dbi gain for a 3 element yagi at about 40 ft. When I built the rhombic and compared it to my 3 ele yagi I found the performance on extremely weak signals near the noise level were essentially the same on both antennas, and the f/b on the rhombic was phenominal. Just what the model predicted. In building the antenna the model told me it didn't make much difference if the wires were 25 feet shorter than I had started with, so it was more convenient to build and attach to trees I had. So I believe the model so far. The second thing I have learned, (and I am building a small collection of my experimental antenna files) is trying to find the best way of getting some gain on 40 meters into Europe from NJ. I started with my inverted vee at 40 ft. I then added a reflector (supported from a guy wire). Then tried converting the inv vee to a delta loop. Wow that was a disappointment. I guess if

you have radiation from only 40 feet up it is not a good idea to distribute that current into elements at a lower angle !!! Then my buddy Yuri, K3BU, told me feed it 1/4 wavelength down from the peak and that would get my angle down and get me some vertical radiation. Easy to do with the program, and Yuri was right.

Oh I tell you this is fun stuff. Much more fun than flaming each other on newsgroups. My suggestion - do a google search, find some software, bang it around on your keyboard, write to me, trade some antenna files, maybe even pull up some wirees into trees.

Oh incidentally, I forgot to mention. Get this. The last thing I learned was how to attach feedlines (the program calls it a transmission line, or a TL card) to two antennas. Make the lines long enough to give you a lot of slack. Then you can move your two active antennas all around and see what kind of pattern you get. Put them end to end, change the spacing. Put them in front of one another, like a JK beam and change the spacing or the lengths. Cool stuff, really cool stuff.

I have flown through dry snow over the Great Lakes that completely desensed the receivers in the airplane - and this was a plane equipped with static discharge wicks... Rising noise to a roar, big discharge POP, receiver back on line for about 3-5 seconds until the rising roar blocks it up again- total cycle 15 to 20 seconds, only able to hear ATC for 3 to 5 seconds out of that... Not fun at O'dark thirty, it is 10F outside, you won't survive a ditching into the water, and your VOR receiver can't tell you where Windsor is...

Yes, I believe in P-Static...

4185. Simple FM Antenna, C. Crane, Radio Your Way (Pogo) and Radio Shark (RS)

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-21 16:44:52 UTC
From: "W. Watson" <wolf_tracks@invalid.com>
Message-ID: <8Syih.35833$wP1.4846@newssvr14.news.prodigy.net>
Source record: 47709

I had an occasion to talk with C. Crane today, and got onto the topic of an FM Antenna for small digital radios. I have the two mentioned in the Subject line. The agent menioned using just a sinple 5' wire for this purpose.

I've not had good luck getting FM reception with RS, and have tried a simple dipole without much luck. I live in the Sierra Foothills at 2700', and the trouble is with stations in the Sacramento area (60 mi) and Chico (75 mi). It occurred to me the simple 5' single wire antenna provided with Pogo has been very effective in improving FM reception, so I put it on RS. Practially no difference with or without it. What's up with that?

Note that RS looks like shark fin, and has a built in FM and AM antenna, and a jack to plug in an external FM antenna. The RS is plugged into a USB port and it is very much like Tivo but for radio.

Any antenna/receiver combination is likely to be sensitive to
p-static. Some more than others obviously. An indoor, heavily
insulated folded dipole connected to an differential input receiver
would probably not receive much - so I'll give you that one even
though I never claimed it would. Happier now?

I will use a pulley. The branches I want to use are very high. I cannot throw or even use my slingshot thingy for this. I have a handyman who has agreed to climb the trees in the spring. I will get everything ready this winter.

I have some large trees on each corner of my lot. I can probably get 50 feet up.

I was going to use nylon rope to attach to the trees but I read that polyester rope last longer. It is even cheaper. I erroneously thought that the more expensive nylon would last longer.

The only time I've used it extensively was years ago in the high arctic. We had a point-to-point circuit with a place about 800 miles to our south (most places were to our south!) using 5597.5 CW and later, SSB. Most of the time it was fine, day or night (and the days and nights are six months up there). Occasionally conditions would black it out and we would be forced to revert to LF.

Of course we were using power levels a tad higher than amateurs are being permitted on the band. Our CW transmitter was 200w (though we had the loan of an 8KW transmitter and a rhombic for a while) and the antenna was a dipole. The SSB that replaced the CW was about 2KW. The LF was 2KW on 170.5 and eventually was changed from CW to RTTY.

Another frequency in wide use at that time was 5680. It was used for AM air/ground comms. I remember one day working an RCAF Herc below the equator on a run from Peru to Australia. He was calling Honolulu and they couldn't hear him for some reason and since I knew the aircraft and the pilot, I called him and got his position report for air traffic control. They were a little taken aback by where the report came from, but hey, if the path works, use it! This was in daytime and, if I remember, a daylight path all the way! (Though I could be wrong about that, it was more than 40 years ago).

As I understand, black Dacron Polyester is the good stuff. They have
it at AES, the Wireman, RadioWorks, etcetera... I've been using some
surplus olive drab Dacron I got from RadioWorks that is really long
lasting and blends in nicely... Radioworks, by the way, has good
marine-type pullys if that's the direction you're going.

sorry, i'm not going to bother trying to argue with you point by point when
you don't believe in 100+ year well proven theories and insist on writing
your own based on misunderstanding of a few figures in a textbook. learn to
read and write the formulas, then write your own paper describing your
theory and why it is different than what is already well published and
accepted.

or even better, build your antenna and try to sell it.

Thanks Bob,

I did not even think to get pulleys and rope from amateur radio supply
places. I will do some shopping there very soon.

What do you think about feeding the dipole with some sort of balun?

You'll want a 4:1 balun if you'll be using coax.

Sorry, I thought you were claiming equal magnitudes of noise for two
dissimilar antennas.

> You seem like a guy who'd pick a fight with his own shadow sometimes,

Sorry, I seem to have inferred something you didn't mean to imply.
I believe I can prove the difference in the two antennas using EZNEC
but not until I get back to my home computer.

Yes I am sure they are. From time to time Yuri and I try to get things going here, to get participants' minds back onto antennas. It's a tough road.
So instead, Yuri and slop around in the mud fixing up old antennas and towers and
having our antenna discussions in person.

Buying pulleys at radio supply places is as bad as buying at a marina. Get
the stainless stuff at your local hrdware for about half the cost.

I PUNCE

4200. IMD products from VSWR meters

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-22 07:46:15 UTC
From: Owen Duffy <none@no.where>
Message-ID: <Xns98A1BD31D5CADnonenowhere@61.9.191.5>
Source record: 47724

I see in the Wikipeadia entry for SWR meters the following:

"When not actually measuring VSWR, it is best to remove the ordinary type of passive SWR meter from the line. This is because the internal diodes of such meters can generate harmonics when transmitting, and intermodulation products when receiving. Because active SWR meters do not usually suffer from this effect, they can normally be left in without causing such problems."

I have seen this advice from time to time, and having done some back of the envelope calcs, I wonder at the accuracy of it.

Has anyone seen reports of measurements of the level of harmonics and IMD products in the main line caused by the diodes of VSWR meters?

Owen

I'm sure you do, Wabbit. In fact, I don't believe you even need a
partner to help you. You "punce" all by yourself.

Hi Owen,

It sounds like sophistry. In years past when the FCC was more
vigorous in chasing spectrum trash, they would have nailed this down
for the transmit side. Even barring that argument, nearly every piece
of gear produced in the past 30 years has a built in SWR meter. Any
IMD from those (and, by abstraction, external units) is probably 50dB
to 60dB down.

Someone I used to work with spent a long time trying to suppress the harmonics from a model aircraft radio control transmitter, only to find that they were generated by the detector diode in the o/p power meter.

Also in the UK it is a licence requirement for CB that power/vswr meters are only used for setting up and are removed for normal operation.

Hi David,

The objection arises out of your commingling radials in the discussion
where the dons never asserted an image theory for them. Can you quote
any source that does? (Let's try proving a positive.)

Let's just cut to the chase, vis-a-vis radials. These elements serve
to balance and match, not to propagate (in the sense of ground
reflections). In fact, when all the radiative contributions of a
ground plane (radials in a plane) are considered, they are self
negating.

If we were to consider the aspect of this image theory (reflection of
a wave); then those radials would have to consume both a lot of
distance out from the feed point, and a lot of real estate. By any
standards found in the market place, or in implementation, this is so
rare as to be exceedingly exceptional. Commercial AM antenna radial
fields DO NOT come close to this either.

And considering that 3rd order transmit IMD from some newer rigs is
coming in as bad as just -20dB, I wouldn't worry about SWR meter IMD!

It seems like the loose coupling of the diodes to the transmission line
would limit the effect to whatever the coupling ratio is as an upper
bound.

If you're applying a signal to the diodes that's already 20-30dB weaker
than the power going to the antenna you're already doing pretty well
compared to, say, an FT-857's transmitter output.

We up here in Alaska have used the 60 Meter Band for many years. We also have a State Emergency Calling Frequency of 5167.5 Khz that is available to ALL Radio Services located inside the State of Alaska. With the NEW Rules that became active on Dec.15th, we are now allowed to hold Preparedness Drills as well as Nets on this frequency, and communicated with the Alaska Private Fixed Stations, and Public Safety Stations thru out the State. I have many years of experience using the Alaska Private Fixed Frequency 5164.5 Khz (Working Frequency associated with 5157.5 Khz

Calling and Emergency Frequency) Also note that Stations using
5167.5 Khz are allowed 150 Watts PEP Tx Power, including Ham Stations.

Owen Duffy wrote:
"Because active SWR meters do not usually suffer from this effect, they can normally be left in withoout causing such problems."

Ordinary meters needing only r-f to power their indicators can also be left in the line with no visible effect because their demand for r-f is very small.

Insertion loss is specified in the Bird Model 43 Instruction Book between the 50-ohm line and sensing circuitry. Specification is 53 dB down between 512 MHz and 20 MHz. Coupling decreases to 70 dB down between 10 MHz and 2 MHz.

The 30 microamp d-c meter and its associated circuitry need negligible r-f power from the line for nearly all ranges.

60 dB is a power ratio of one million to one.

Best regards, Richard Harrison, KB5WZI

Hi All,
The 30M band is also a phone band during daylight hours in the Southern
Hemisphere. Still not much traffic though!

Glad to see the US finally did the right thing with regard to CW.

Hi Jim,

Seems I misunderstood your original post as suggesting that each
incremental charge produced a pop.

I see that the typical current density of rain in a storm is on the
order of 0.1 - 1 uA/square meter. Taking the usual obscene liberties
with priors, that's on the order of 60 - 240 pA for a 40 meter long wire
with a diameter of 2 mm.

The average voltage developed at the receiver front end (50 ohms)would then be on the order of 12 nanovolts (240 pA x 50 ohms). This is obviously many orders of magnitude less than reported p-static signal levels.

Using your capacitor-coupled amplifier example, a continuous, average current of 240 pA would be more like DC than what we seem to hear. I am persuaded that there may be some kind of relaxation process going on in which the charges build to some breakdown level and appear as a pulse (significantly greater than 12 nV) at the receiver input. But what breaks down? Diodes? Presumably we are not talking about arcing here. Does anyone recall this phenomenon in the vacuum tube receiver era?

Also unknown is the state of charge of the ungrounded antenna wire just prior to the acquisition of an incremental charge. Is the antenna at some high positive or negative potential just prior to impact, allowing a small incremental charge to cause a breakdown?

What I think we do know is that there are sometimes charged particles (dust, rain, snow, etc.) that impact an antenna and cause a characteristic type of noise in the receiver. Exactly which particles, with which charges, and under what conditions of pre-existing charge in the antenna do we see such noise and at what signal levels?

I'm sort of at the analogous point of noting that crop growth is correlated with some periodic level of rainfall, without a clue as to the mechanism by which the raindrops and plant growth are related. ;-)

Appreciate your comments, Jim.

73,
Chuck

Kraus, _Antennas_
Johnson, _Antenna Engineering Handbook_
Lo and Lee, _Antenna Handbook_
Balanis, _Antenna Theory_
King and Harrison, _Antennas and Waves_
Jordan & Balmain, _Elecromagnetic Waves and Radiating Systems_
King, Mimno, and Wing, _Transmission Lines, Antennas, and Wave Guides_
Brown, Sharpe, Hughes, and Post, _Lines, Waves, and Antennas_
Stutzman & Thiele, _Antenna Theory and Design_

to name a few. I'm sure there are many more, but those are the ones
currently on my shelf.

Several of these authors use an image to analyze a vertical antenna over
a perfectly conducting ground of infinite extent. None use it for any
other situation, including elevated radials. And for a very good reason
-- it's not valid for other situations.

Roy Lewallen, W7EL

the noise is caused by corona on the antenna due to the electric field
between the ground and cloud. this field can be many thousands of kv per
meter which is enough to cause sharp points and tips of elements to generate
corona which makes the hiss and pop noises.

Hi Dave,

Yeah, that's another hypothesis. One might even be led to reason that insulation would prevent these corona discharges. Yet, it is quite easy to charge a grounded antenna (completely insulated) with the electric field that exists between the ground and clouds (or air masses).

So we have at least two candidate causes for what is called by some "precipitation static": charged particles physically impinging on the antenna wire; and electrostatically induced charges that produce corona discharges. Are there others? Can both processes occur simultaneously? Are the two processes simply different paths to the same end: corona discharges?

Do we have a way to test these competing hypotheses?

73,

Chuck

For clarification, I didn't say those words and I don't represent that position at all. They are a partial quote by Richard Harrison of my quote from Wikipeadia.

>
> Ordinary meters needing only r-f to power their indicators can also be
> left in the line with no visible effect because their demand for r-f is
> very small.
>
> Insertion loss is specified in the Bird Model 43 Instruction Book
> between the 50-ohm line and sensing circuitry. Specification is 53 dB

I think "insertion loss" has a different meaning, but I agree that the coupling loss to the sampler is typically very high.

My back of the envelope calculations were:

Looking at typical Breune style ham external VSWR meters which have a voltage divider of 1:60, the coupling loss (voltage sampler + current sampler) is probably in excess of 30dB. Conversion loss (power into the sampler to harmonic/IMD out is probably in excess of 40dB. Total round trip loss is probably 30+40+30dB, which is far better than the performance of a typical PA.

If there was substance to it, it is a bit of a worry as others have noted, most transceivers have a built in coupler for at least protection purposes.

I know that there were versions of external SWR meters with a "power" measurement function that indeed had a diode receifier connected directly to the through line, and the coupling loss term I discussed above would not apply. Similary, an "RF Power Out" using similar circuitry was incorporated in a lot of low power transmitters (eg CB). Nevertheless, conversion loss (as an RF harmonic/IMD generator) in the rectifier circuit is still probably enough to ensure products are below normal PA IMD products.

But... the question was really has anyone seen credible measurements that might support the Wikipeadia line?

It is probably yet another archtypal ham myth about VSWR, and since it is rarer, it would be a real gem for the "knowing" to trot out.

Owen

4219. Hemispheric coverage CP antennas

I have become interested in trying to develop antennas for hemispheric coverage for circularly polarized signals. My interest in related to 137 MHz weather satellites, but not restricted to that frequency.
I have one concept for receiving NOAA satellite signals that is slightly better than with a Quad Helix.

My reason for this post is to try to communicate with anyone with interest in this antenna development as a hobby. That is - I'd like to be able to exchange ideas with another amateur antenna hobbyist.

Jerry

the easiest test is done for us, all we have to do is observe.
'precipitation' static can occur without rain or snow, and it sounds exactly
like the noise when there is rain or snow... so i say the corona effect is
the major cause and any effect from charged particles is secondary and much
smaller.

Because active SWR meters do not usually suffer
from this effect, they can normally be left in without causing such
problems

Can anyone clearly explain what is an "active" SWR meter? I would presume that the line is decopled from the diode by means of an amplifier. Is that what they mean?

You can easily charge up an insulator with a static charge. A comb is
usually made out of an insulating material. Run one through some hair
and it will pick up small pieces of paper. (I use my wife's hair.)
Secondly, particles don't have to be charged to create a charge on
an antenna. They just have to touch it and be pulled off. Google
triboelectricity. (I think I spelled that right. If I didn't, ask
Cecil how it's spelled. He knows.) Yes, there is more than one way to

charge an object to the point of creating corona discharge. Make a small Van de Graf generator and try that. You also might want to charge up an insulator (your comb), touch it to your antenna, and measure how much charge was actually transferred to the antenna. Discharging insulators is sometimes difficult because they're, well, insulators and charge doesn't move around on them readily. Sometimes you have to use Polonium 210, or a torch, or a specially built fan to accomplish this. (You can buy a Polonium brush. The manufacturer warns against taking it apart to see how it works, though.)

Make a homemade field mill and measure the earth's electric field during a time when there's corona discharge from your antenna. A large natural electric field from a big, honking thundercloud could easily cause coronal discharge on your antenna under those circumstances. There are lots of things a dedicated amateur can do to measure static electricity, and, if he doesn't get killed, the effort is worth it. Just making up theories out of the clear blue, however, without any attempt to test them, is just a waste of time.

Hi Tom,

Don't know toward whom your post was directed, but I'll comment anyway
--if that's OK. ;-)

I'm quite comfortable with your statements on electrostatics. Regarding
theories and testing, however, there is perhaps more to be said. A lot
of anecdotal evidence of p-static has been described, more or less
roughly, in the group. That's really great. But before meaningful tests
can be designed, I think an attempt at understanding the mechanisms
behind the various p-static reports should be explored. A big part of
the problem is that we probably can't cause the p-static to appear on
command in our testing laboratories! Moreover, we are pulling stuff out
of the air if we believe all reported cases of p-static arise from

similar conditions. In more blunt language, I most humbly suggest we seem to be having difficulty understanding what is going on and I hope that the more it is discussed the more likely we can achieve closure.

We have, if I am following correctly, at least two suggested causes for the observed phenomena. Charge impingement and electrostatic induction. Yeah, they're both electrostatic actions, but very different. They can even occur simultaneously, which adds additional complication. Moreover, we're concerned with an electrodynamic consequence (a current in the receiver input circuit) of some electrostatic event(s).

It is beginning to appear that in some minds, these two explanations are merging: both can cause coronal discharges. I am somewhat skeptical about the induction mechanism, at least in the case of an insulated wire. Here is why: if the field is strong enough to cause coronal discharge of an insulated conductor, it will also cause coronal discharge of almost everything in the vicinity. I think a very strong field would be required for that to occur, surely much more than 10 KV/meter. Didn't W8JI describe something like that with discharges from trees?

Electrostatic induction will not generally transfer a charge to an ungrounded conductor. It will simply redistribute the free charges thereon so as to render the net field within the conductor zero. In other words, only charged object(s) brought into direct contact with the conductor will impart a charge. An electroscope comes to mind: bringing a charged comb near the electroscope will cause the leaves to fly outward, but no charge is transferred; the comb (i.e., its field) merely redistributes the charges preexisting on the electroscope.

For a grounded wire antenna (even one grounded through the 50 ohm input impedance of the receiver), there is a vast supply of charges that can be "induced" by charged clouds into the conductor from the earth itself. All the free charges in the wire (rather than 50%(?) of them in the insulated case?) may make coronal discharges possible at lesser field strengths.

I hope we can continue to kick this around.

73,
Chuck NT3G

It appears Art has picked up some phrases haphazardly and is trying to apply them to antennas some how, If I remember correctly doesnt Gaussian field apply to statistical distribution. Been a long time since I had statistical analysis back in the early 70s but I think this is also refered to as a "normal distribution".

In this neck of the woods "active" usually means the meter has
peak reading circuitry that requires power to operate. In general,
as far as ordinary peak reading meters, this is the most accurate
type as far as trying to read voice peaks. The better ones use
fast acting LED's as the meter.
A "passive" meter is one that uses capacitors to give the meter
a "hang time" to sort of read peaks. But it's not as accurate, and
almost always reads low. "20-25% worth" for the average meter.
The cross needle meter in my MFJ-989C is an example of a
passive meter circuit. I call it "psuedo peak reading". :/
I also built a passive circuit into my old green cube heathkit
meter. It has a switch on the back to switch the caps in or out.
Naturally, the passive meters require no power to operate.

Precipitation static requires static transferred from charged
particles of rain, snow, or dust. Corona requires the ionization
of air. These two phenomena can exist together or separately.
Ionization of air requires a certain threshold. Precipitation
static can exist either below or that threshold or be the cause
of the corona. Corona can exist in the absence of precipitation
static. There are other kinds of static, e.g. propagating EM
static from numerous sources.

Hi Chuck,
Read "Meteorological Aspects of Precipitation Static" By
Lieutenant Robert C, Edwards, U.S.N.R., and Captain George W. Brock,
U.S.A.A.F. from the Journal of Meteorology, Vol. 1, Number 4,
December, 1945. If you Google "Precipitation Static" you can
find a pdf file of it. They actually went up in three different
airplanes, an RB-37, a B-25D, and a B-17G and did some measurements.
You might be interested in their methods and conclusions.
73,
Tom Donaly, KA6RUH

Many declarative sentences, Cecil, but you're wrong, as usual.
When are you going to actually do some meaningful experiments to
find out whether you're right or not?

Hi Jimmy

By my standards, you are *Right On* on all you wrote. I'm pretty sure
Gaussian distribution of power across a radiating plane results
(theoretically) in zero side lobes, That is also a very poor distribution
when gain is a goal. I think the term Normal is synonymous with Gaussian
when referring to aperture distribution.

I dispute part of that. On receive, the diodes are not conducting, so they
won't generate IMI products. If they were a problem, then every receiver
front end in the world would be a worse problem.

4235. Question about 20-meter monoband vertical (kinda long - antenna gurus welcome)

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-23 04:34:19 UTC
From: Zommbee <devarim@hotmail.com>
Message-ID: <LLCdnQlHxY7rLxHYnZ2dnUVZ_u2mnZ2d@comcast.com>
Source record: 47759

Hello all - I hope someone can help me figure this one out:

I just put up a 20 meter monoband today. Been working on it for
a week of nights, and got it in the air when I got off work today early.
I used the 234/f formula and cut it for around 14.100 mHz which
gave a length of 16 feet 7 inches. It was a a bear to hoist
up (my XYL helped me) - the base is only about 12 feet off the
ground (my only mounting option). I put up 4 identical-length
radials, 3 of which are quite close to 45 degrees, the 4th is is
only about 10 degrees down due to mounting issues. The coax
feed is about 40 feet (RG-58 - good quality). I wound a
4" form with 10 turns at the base of the antenna and another 10 turns
at the transmitter to try to keep the feed line 'out of the loop' (is this
wrong?)

I find it is REALLY broad - is this normal for a monoband? I
have only used trap verticals before. The SWR is 1.5:1 from
14.025 up to around 14.200 - very little change. It is actually
hitting resonance somewhere around 14.600 (using MFJ meter
when out of band). (See 'Problem' below)

Construction: Copper water pipe, 10' of which is 3/4" then 5' of
1/2" and finally a 1/4" section that is the 'tuning end'. For the radials,
I made a circle of 14-ga antenna wire around the 2x4 wood support
on brass hooks (one each side) that support the radials - diameter of the
radial 'circle'
is about 6" or so - not very large circle. Radials were cut exactly the
length of the antenna and are well insulated with ceramic eggs and poly
line, angles as stated above. Copper element is suported by 1.5"
ceramic stand-off insulators from the Oak + 2x4 treated wood support.

Problem: My TS-440s (AT) without the tuner only puts out
about 60 watts in CW and RTTY segments, and only hits
full power in the upper end of the SSB band UNLESS I use
the internal tuner - then I get a full power output in CW since
the transmitter is 'faked' into believing it is resonant. During my late
night (illegal 30 second) test, I get 110 watts at 14.600 with almost
no visible SWR - clearly the resonant frequency...

Questions:

Question 1: Are mono-band verticals always this broadbanded
or do I have something wrong? It does not seem to have much Q.
SWR only very slowly creeps up over the band... (I loaded at
power at 14.600 VERY FAST late at night - please don't give me

a ticket Mr. FCC! - and the SWR was almost unreadable it was
so low - the MFJ meter is right - that is my resonance point). My old
4BTV was 'sharp as a tack' in tuning... VERY high Q. Are mono-bands
less selective?

Question 2: Am I being overly concerned? I can use the Auto Tuner
in the TS-440 to make it happy without any problem... is this ok?

Question 3: I built this antenna to be good for my Oak Hills QRP rig -
I had hoped not to have a tuner in the loop - I use a Kenwood AT-180
when I'm not on the TS-440s - is the loss that significant? Again, am I
being
overly concerned, since the AT-180 very easily tunes out the difference?
Or should I tweak on this antenna until it is perfect for CW SWR?

Question 4: I understand the radials are a major part of the design - could
it
be that the 'formula' (234/f) was correct, but somehow my radials are a bit
off
and could make the difference without adjust the 16' 7" vertical length?

Question 5: Since I made the 'radial circle' about 6" diameter around the
base
of the antenna, but then connected the radials (cut exactly the length of
the
radiator, less the 'radial circle' of wire around the base, attached to the
brass
hooks used to support the radials) could this be de-tuning the antenna enuf
to
raise the frequency (seems it should LOWER in frequency if anything)?

If you 'wiser' hams advise, I'll certainly drop the antenna (after cutting
the radials
loose) and enlist my XYL to help again, and add a couple of inches of
copper to
the ends (and too the radials) and do it all agin... but it was not easy to
do in the
first place... (The antenna only weighs 25 pounds, but OMG lifting it up to
position
felt like it weighed 250 pounds!!)

How it performs: I found during on-the-air tests that SOME signals were
significantly
better over my 200' "random wire" and some were worse. Consensus was that
there
was almost no difference 'short haul' (coast to coast). Some signals are
not at all
audible on my 200' wire, but S7 on the vertical, for example... no DX today
so no
idea if the low angle is working or not...

But what about at QRP levels? With my AT-180 tuner? Just seems that I should hit
my ideal SWR in the 14.060 range - rather than 14.600 despite the broad-band performance.

What do you recommend I do at this point? I have the whole weekend to either play with the
new antenna or quit obsessing over it :-)

Thanks for replies and putting up with my long-winded posting. Please either post here
or at my email address of devarim@hotmail.com

many thanks,

Dave WB7AWK

Sounds fine to me.. A monoband on 20m will seem fairly broadbanded.
Ground losses can add to this, but you are stuck at your height, so
it's
not worth worrying about. All you could do as far as that is add more
radials.
You are almost a 1/4 wave up, so things could be worse I guess..
As far as the match, 1:5.1 is fine as long as your radio is happy with
it.
That's the only thing that matters. Trimming the antenna will not help
performance unless the radio requires it to put out full power. If you
are
putting out full power, "most rigs should at only 1:5.1", thats good
enough.
If not, you might want to consider tweaking the lengths a bit. Most
likely
you could just add an inch or two to the radials only, if you wanted to

avoid pulling it all down. That should be enough to dial it in. You
won't
lose too much using a tuner, but if you are running QRP, I'd avoid it.
There is no real need to use a tuner with that antenna. I never use a
tuner
if I don't need it.. Which is about 98% of the time.. I have a big
tuner,
but the only thing that really sees any use is the wattmeter that's in
it. :/

A simple way of stating what I'm after is why does a simple 5' wire work
better on one FM radio than another, when both radios are used from the same
spot? In fact, why does a simple 5' wire work almost as well as a folded dipole?

FM signals have a wavelength around 3 meters, so a quarter wave whip antenna would be in the range of 75 cm long. Not fitting that into the fin, are we? A built-in is a bad-deal compromise for FM.

How was your "simple dipole" connected to the RS? With two wires, perhaps one to the FM antenna terminal and the other to common on the radio? You don't say whether the jack was a coaxial jack or just a single-conductor pin jack.

Not every antenna needs to be connected with two wires to work, but it's true for the ones that work the best on FM broadcast. They're either coax or twinlead -- two conductors either way. If EXT FM ANT is just a pin jack, I'd get to the common electrically by soldering a wire to the negative battery terminal and running it out of the case to connect to one of the antenna leads. A cap in that lead will isolate any DC path off the antenna jack.

A folded dipole is common antenna for FM -- easy to build, easy to hang on the wall or tape on a stick for elevating outside a window. First ones I ever saw were on my high school A/V Dept televisions. Cut for Channel 13, the local educational station, and taped to a stick. Worked.

Dave,

I guess that you are hoping that with radials sloped down at 45 deg, you should approach a 50 ohm feedpoint at resonance.

My experience is that sloping the radials tunes them high, in other words, they need to be a little longer than were they are 90 deg to the vertical element. Try clipping a short length of wire (say a couple of feet) to the ends of the radial, just hanging down, and see what it does to the feedpoint impedance. You can slide them away from the end to lessen the effect. The outcome might just give you a hint of what needs to be done. Remember, measure twice, cut once!

Re the tuner loss, they should be very low for the VSWR you have discussed. Nevertheless, if you planned to have an antenna that shouldn't need a tuner, I can understand why you might want to pursue the reasons why or why not. It is an excuse for learning or frustration, depending on your point of view.

As a matter of principle, I avoid using tuners like the '440's, they are the achilles heel of those radios when the relays become unreliable.

BTW, one of the techniques for obtaining a match to 50 ohm feedline from a groundplane antenna is to tune it a little high, and shunt the feedpoint with an inductor or s/c stub. I drafted some notes on the topic at http://www.vk1od.net/QWVmatch/QWVmatch.htm . This is probably not the answer to your problem, since your 45 deg radials should lift the feedpoint Z close enough to 50 ohms and closer than VSWR=1.5 that you are observing right now.

Driving the diode with a wideband RF amplifier would have the following
advantages:
(a) allow a lower level of RF sample to be used (higher tap-off ratio).
(b) further minimise the possibility of diode distortion products from
getting back into the RF through-signal.
(c) drive the diode at a higher level, thus improving the RF-in to
DC-out linearity.
Do any SWR meters do this?
Ian.

This sounds very much like the requirement faced by GPS receivers, so you might also try some forums dealing with that technology. To my knowledge, patch and quadrifilar helix antennas seem to be the most commonly used.

If by "active" one just means that the meter requires power, then I would see little difference between an active and a passive circuit as far as intermodulation is concerned.

As a matter of fact if, in an "active" meter, the amplifier (or the active display) follows the diodes, there would be no difference at all (as to intermodulation) with respect to a passive meter.

If the amplifier is instead put before the diodes, the intermodulation products generated by the diodes (if any) can get coupled to the line.

In summary the distinction is between a circuit in which the diodes are directly coupled to the line and a circuit in which there is an isolating stage between the line and the diodes. And not between a passive and an active circuit.

The belief that SWR meters produce harmful harmonics probably dates from the 1950s, when TV coverage was low, and many viewers had to drag in weak signals from a considerable distance. I'm in the UK, and the signal level on UK Channel 5 (around 65MHz) was only about 30 microvolts. Oh yes, the picture was snowy!

Obviously, the 2nd and 3rd harmonics from transmitters operating on the higher HF bands could easily wipe out TV reception, especially lowband (our 'Band 1').

As well as using the usual 30MHz lowpass filter, some amateurs went to considerable lengths to suppress harmonics emanating from the transmitter itself (with particular attention to the screening and bonding of the metalwork, and the filtering of all leads (mic, key, power). Without this, there was little point in even thinking of fitting

a highpass filter etc to the TV set.

I believe there were one or two cases where the final vestiges of interference were traced to harmonics being generated in the SWR meter. This was cured by ensuring that the line-up between the transmitter and the antenna was TX - SWR Meter - LPF - ATU (if used) - Antenna. Doing it this way ensured that any harmonics from the meter were removed in the LPF and (to some degree) the ATU.

The line-up above is the one which I always recommend should be used if possible. Generally, there is no reason not to. It is good engineering practice. But as to whether it is always essential? I suspect that often it is not.

hi

just wondering how much and how to calculate the loss in some common coax for ex lmr400 over a given bend

naturally i mean not to exceed it's bend radius spec

but i figure electrons want to stay in motion and 'prefer' to go straight so if i make a bend some of that energy i recon will be lost

a 90 degree bend is within spec for the above and i wonder how much i loose

i know some of my variables lmr400 90bend and for ex 20m and 70cm

thanks

the only effect you will notice is if the bend is tight enough to move the conductors enough to change the characteristic impedance. electrons are moving so slowly compared to the fields that their individual energy is not affected by physical conditions of the coax in any way that you or I will ever measure.

Hi Tom,

Thanks for the reference. Quite an interesting article.

My one problem with it after a quick reading is their autogenous/exogenous electrification dichotomy. More particularly, their notion of exogenous electrification, which " . . . occurs when an aircraft flies through electric fields previously established by a charge separation in the free atmosphere."

Not sure it is important to the physics exactly how the electric field was established, but taking the airplane to be an isolated conductor in an electric field, I wonder how "electrification" can take place.

Perhaps 60 years ago we used different terminology, but electrification usually refers to contact charge separation. Since there is no assumed contact with charged particles in the exogenous electrification mode, electrification may be a misnomer today. As I suggested in an earlier post, all an electric field can do to an isolated conductor is redistribute the charges preexisting on the conductor. Of course if the redistribution of charges leads to coronal discharges favoring either the positive or negative "end" of the plane, then the plane could acquire a non-zero net charge (i.e., be electrified). The authors don't give a hint that this is what was envisioned, though.

I'd appreciate comments on whether such a thing as "exogenous electrification" as described by the authors makes sense to anyone else.

Source record: 47774

Your bandwidth is correct for a 20 meter ground plane. At 14 MHz, covering the entire band is not a problem.

To drop the resonant frequency down to what you want, you have three choices:

1. Add length to the vertical section.

2. Add length to all the radials equally.

3. Insert a small coil in series with the base of the vertical section. Start with about one turn, one inch in diameter.

Since you say this thing is hard to get up and down, I would recommend either 2 or 3. Either one will do, but my personal preference is for the coil *IF* you can insert it in series easily. If not, go for the radials.

It's good that you have the SWR analyzer. It will save a lot of hair pulling.

GL!

the current in the object is at least part of the story. if the object is close enough to the antenna it can also change the currents in the antenna itself and distort the pattern.

Hi Roy

I have tried to locate someone in the commercial level of antenna development to "show off" what I have uncovered with this hemispheric coverage antenna concept. I have no interest in making money with this concept. But, I am proud to have developed it.

It would wrong for me to say that this concept is any better than a Quad Helix for anything except NOAA satellite imaging. Its main superiority is its sensitivity to signals at the horizon, and thats no more than 6 dB. A major benefit associated with this design concept is it's being non critical to manufacturing tolerances. So, I thought it would be interesting to guys who build their own APT antennas.

The concept is -- an array of two pairs of 1/2 wave dipoles spaced about 1/4 wave apart and tilted slightly from vertical. One pair is fed in phase with each other. The other pair is also fed in phase with each other, but 90 degrees later than the other pair.

Where are your experiments that prove you right and me
wrong? Where are your references for such?

All the experimentation has already been done by others,
Tom, and pretty well documented in publications available
on the web including a host of governmental and university
publications so I would be wasting my time. It is possible
that I misunderstood something but impossible that there
has not been enough experimentation. Wishing that all static
is caused by ionization of the air is just a pipe dream. There
would probably never be enough precipitation static on a
well-designed folded dipole to result in ionization of the air
but certainly enough to hear in a receiver.

Hi Chuck,

The author wasn't particularly interested in the electrification as he was the conduction and subsequent discharge. In actuality, what is described as exogenous electrification is no different from autogenous. The air currents described simply convect smaller particles as has been described in subsequent years in other aviation material starting with "Atmospheric Electricity," Chalmers, J.A. - 1967; or earlier with "The Fair Weather Atmospheric Electric Potential and its Gradient," Clark, J.F. 1958.

Normal convection builds up a charge stratification on the order of 190 V/m at ground level, but declines to half that a mile up. At that same mile altitude (above ground level) charge density increases 1000%.

Needless to say, aircraft at different altitudes in identical, clement weather are subject to vastly different fields.

Hi Rohit,

An answer in detail is much too lengthy to present in one response.
The first consideration is the current amplitude and phase in the
antenna, the second consideration is the amplitude and phase in that
nearby conductor, and its distance to the antenna - the physical
distance is actually a third phase consideration.

The pattern is a combination of all amplitudes and phases as viewed
from an extreme (more than 100 wavelengths) distance.

Hi Myles,

Any particular electron is not going very far, or very fast in that direction. In fact, if you wanted to attach a message to an electron, you could deliver the message faster by walking (much faster). Technically, this focus on the electron falls into the topic of Drift Velocity which in wire is literally as slow as molasses. Rather, it is the speed of charge transfer that does the work we are familiar with and with work, work lost to heat which returns us to your concern of bend radius.

Hi Richard,

Thanks for the second opinion and additional information. I agree with
your interpretation.

73,

Chuck

Well, the FT-857D comes in at -21dB according to ARRL lab tests.

A FT-1000MP is only 6dB better at -27dB.

An IC-746 is -23dB, as is an IC-756 (non pro, pro is -31dB)

An IC-703 is -24dB

The absolute best I can find in the ARRL comparison charts is the
TS-950SD which comes in at -42dB

So we don't need to worry about SWR meters that can, at most, cause -40
or -50dB IMD products.

Dan

> I used the 234/f formula and cut it for around 14.100 mHz which
> gave a length of 16 feet 7 inches. [snip]

Thanks for all the replies. I added about a foot to all 4 radials and now the antenna has an unreadable SWR (1.0+something small) from 14.005 to 14.200, where it barely starts to wiggle the needle! I had no idea a mono-band vertical was SO BROAD! Now most medium distance stations (1500 - 2500 miles and up) are easily 2 S-units above my 200' wire. Seems to be working quite well!

Thanks for all the assitance

Dave WB7AWK

4268. Proximity effect of 2 different vertical antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-23 22:59:32 UTC
From: Zommbee <devarim@hotmail.com>
Message-ID: <E-CdnddZ15xPKRDYnZ2dnUVZ_ue3nZ2d@comcast.com>
Source record: 47642

Hello again,

How close to my 20-meter mono-band vertical could
I put a 15-meter version of the same? I have a great
spot that's only about 10 feet away - will there be
negative interactions of the two? (Of course, it would
be nice if the sun had a few more spots!)

Thanks

Dave WB7AWK

4269. Re: distortion of the antenna pattern

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-24 00:17:02 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <12orho4sq241h5a@corp.supernews.com>
Source record: 47644

The phenomenon is known as "mutual coupling". The field from the antenna induces a current in the conductor. That current produces a field which does two things: it vectorally adds to the field from the antenna, which alters the overall field; and it in turn induces a current into the antenna conductors, which alter the field from the antenna.

A quantitative study of this phenomenon is complex and requires solution of Maxwell's equations as well as fundamental equations for radiation. The latter can't be solved at all in closed form, and the former can be far from trivial if the geometry isn't extremely simple. Many approximations have been developed over the years, but they can be applied only to a few simple geometrical configurations. You won't have any trouble finding an abundance of information in any antenna textbook or in papers of various publications like the IRE/IEEE Proceedings.

But with a home computer, you can now get very accurate solutions to even very complex geometries in seconds. They'll tell you not only the overall pattern, but the currents on each part of each conductor. As the author and seller of EZNEC, I recommend that you download the free demo version of that program from http://eznec.com. There are, however, a number of other readily available programs which all give essentially the same information with equal accuracy.

Isn't that more like one antenna with two feedpoints. The 15m qw vertical at 3m distance from the 20m antenna is just within the radian sphere, so inside the near induction feild zone.

It depends.

This is an ideal problem for an antenna modeling program. You should be able to get a pretty good answer from the free EZNEC demo available at http://eznec.com.

---------- REPLY FOLLOWS ----------

It's not broad because it's a mono band vertical. It's broad because
of the relatively high frequency, relatively narrow bandwidth and it
being *not* inductively loaded. Try the identical design cut for 80
meters which is a much lower frequency and a larger band (500 KHz) and
you will be singing a different song. :-)

Have fun!

Hi Roy

Last year I "thought up" this super simple concept while driving along the freeway. Thats how simple it is. At that time I had no idea what the axial ratio of the RHCP would be in the "other directions. I could see (in my mind) that it would be excellent RHCP at the horizon, toward North, South, East and West., in free space.
I build maybe 50 different full size models in my effort to improve the performance. I was able to record some decent NOAA satellite pictures with the prototypes so I had strong hopes that the CP in the rest of the hemisphere was "OK".
Richard Clark occasionally helped my clear my thinking while I was building prototypes.. Then one day he suggested that I try modeling the concept with EZNEC. That EZNEC almost takes the work out of antenna design. With the computer modeling program, I am able to demonstrate that the free space radiation pattern shape in RHCP is Very good throughout the hemisphere.

One thing I like about the "Double Cross" concept is that anything a guy builds will work. The design has no tight tolerances on anything if/when the dipoles are phased properly.

I'd be honored to know that you'd look at my EZNEC file. Tell me if you'd consider reviewing one of the antennas that I consider quite good for APT imaging from NOAA weather satellites.

Take 3 pcs of wire, put little temporary tags on them to identify the ends, wind them together on the core. Then wire them in series. Call one end ground and the other end hot. Your high impedance terminals are the hot to ground and your low Z terminals are one winding up from ground, and ground. In other words your low Z is one winding and your high Z is all three windings.

Hi Cecil,

Though I must seem to be coveting the dead-horse-beating trophy, have you found an explanation of how the relatively low average currents that charged precipitation imparts to an antenna cause static? My back of the envelope calcs showed nanovolt-level signals at the receiver from this current. Clearly, adding charges could eventually result in a corona, but how does the typical current density found in a storm result in measurable (i.e., readily detectable) signals at the receiver front-end when no coronas are present? As I asked in an earlier post, is there a relaxation mechanism somewhere in the antenna/receiver system? Where? What determines its time constants?

Are the reported current densities wrong (i.e., not representative of the conditions under which non-coronal p-static is typically developed)? Is p-static somehow anomalous in that it is not found in all storms with charged precipitation?

The coronal mechanism is understandable to me, but the non-coronal p-static leaves me needing a better explanation than I have been able to find.

A special thanks to you for helping to keep the group lively and interesting, Cecil!

73,

Chuck

Here's a link to a brief Navy document (gotta be true!) that gives a simple overview of noise. It claims coronal discharges are the principal cause of precipitation static. No mention, however, of any other, non-principal causes.

http://www.globalsecurity.org/military/library/policy/navy/nrtc/14030_ch10.pdf
14030_ch10.pdf (application/pdf Object)

Evidently, aircraft encounter current densities between 50-300 A/square meter, while typical current densities near the ground from charged precipitation are on the order of 1 uA/square meter. That's quite a few orders of magnitude difference.

Hi Chuck,

From the nature of your questions that follow, your envelope appears
to be insufficient to cover the topic.

>Clearly, adding charges could eventually result in a corona,
>but how does the typical current density found in a storm result in
>measurable (i.e., readily detectable) signals at the receiver front-end
>when no coronas are present? As I asked in an earlier post, is there a
>relaxation mechanism somewhere in the antenna/receiver system? Where?
>What determines its time constants?

There are two mechanisms at work, and they are classically the source
and the load. The source imparts an impulse, the load provides a
complex response. Any impulse's origin is the arrival of a charge.
The load (the antenna feeding the receiver) is very large in
comparison to the volume of charge arriving and all impulses are not
coherent.

Your nano-volt determination appears to neglect the accumulation of
charges which, in turn, does not take into account the reactance of
the load (there has to be a considerable mismatch involved here).

Someone reported being able to hear each individual large
snowflake. Could be that the amount of charge in a large
snowflake or a large piece of dust is magnitudes higher than
in a drop of rain, which I assume is the charge you are talking
about above. In any case, a very large number of particles
hitting around the same time could have a cumulative effect.
I personally have never heard P-static from rain but I think
I have seen it remembered on the bandscope on my IC-756PRO.

This study found that 20% of the observed charges were greater than 1.6
pC. Or, 80% were below 1.6 pC. At least it doesn't contradict your
hypothesis.

As far as I can tell, the "simple" dipole is a single strand of wire wrapped
in plastic. It's supplied by the Pogo mfger. In the shark it plugs into a
single antenna socket for an external. For the Pogo it plugs into what is
called the phones socket. The question remains. Why does this simple wire
work reasonably well in one radio device but not the other? The connection
looks snug in both cases.

See <http://www.griffintechnology.com/products/radioshark2/> and
<http://www.ccrane.com/radios/am-fm-radios/pogo-radio-yourway-lx/index.aspx>.
I'm not sure the shark page is functioning properly. I don't see a picture
at the top, which I've seen before. The antenna socket is near the USB wire
on the vertical section of the fin. A picture of the antenna wire is buried
in the manual for Pogo.

I suggest you put up the 15M and check how much the SWR on the 20M antenna changes. I don't think it will change much at all. If the SWR doesn't move then you don't have a problem.

Also, if you use a relay to disconnect the 15M antenna from it's coax at the base of the antenna then you get a 42MHz resonant half wave which will be even more out of the picture for your 20M antenna.

I'm not sure of the numbers involved, but as someone who has lived in a
300 inch of snow per season and storms with up to 10 inch/hour plus high
winds, that snow static is real and a real pain in the ass. It makes
small pops as it hits, and eventually you will hear a large amount of
noise apparently from discharge. Dependant on antenna type, etc.

I have no experience with dust.

ahh ok thanks guys, i don't know why i was looking at an electron and
thought it wanted to keep going in same direction (objects want to keep
going ...) so i thought that a bend wouldn't have made the electron
'want' to change direction

but i followed what you spoke of, i was thinking more volts and
forgot about rf still made me ponder

but all clear now

thanks again and HAPPY HOLIDAYS !!

While the others have given an explination, I have measuered the loss in the past, did it on 4 pieces about 130 feet long wound in coils about 2 feet in diameter a few weeks ago . Did that to check out the new coax I used to install new antennas at my house to make sure the coax and connectors were installed correctly. While I did not streach the coax out and do another measurment, the losses met the specifications .

Let me make it clear that virtually all of my precipitation static experience has been with wind-blown dust in the Arizona desert with absolutely no personal experience with snow static and very little with rain static. All I know about snow and rain static is what I have read and heard. Here in East Texas, rain is usually preceded by lightning so precipitation noise from rain is hard to detect. I think I saw it on the bandscope display of my IC-756PRO the other day, didn't see any lightning or hear any thunder but, of course, I can't say for certain.

However, I can say with certainty that precipitation static from wind-blown dust can exist on a low humidity clear-sky day and was somewhat proportional to wind speed. Changing over from a bare-wire dipole to an insulated folded dipole reduced the problem to a tolerable level. The folded dipole was less noisy on dry windy days than a bare-wire dipole with a 4:1 voltage balun (DC short) on the feedline. I can't swear that corona didn't exist during receive, but I never saw any glow at night even when I was transmitting 500 watts. Corona should be less of a problem in low humidity like Arizona.

Tom, do you have any experience with bare-wire dipoles Vs
insulated folded dipoles?

> I have no experience with dust.

Add your snow static experience to my dust static experience
and all we need is someone with rain static experience. :-)

One other thought based on Richard C's comments:
Your calculation didn't take reflections in a resonant
antenna system into account which could cause the maximum
voltage to be a couple of magnitudes larger at the antinodes.
That assumes the burst of RF from the discharge is a few
cycles long at the resonant frequency. As an IEEE paper
says, resonance can cause "voltage magnification by coherent
spatial modes".

I need to find a binding for barium titanate powder. I think to use
a silicon glue as binding but I don't know in what proportion .
I am interested too to not very difficult alternatives i.e. to use
other binding , different from silicon , to make compact bariun
titanate powder.
Besides I have found for liquid silicon glue a relative dielectric
constant of about 11 . When silicon became rigid it decrease?

Thanks

just what are you trying to do?? there are all sorts of binding agents you could use depending on the requirements, just about any glue could be used, but they have different mechanical and chemical properties. probably the most durable would be an epoxy, but there are also castable plastic resins like the ones used for hobbyist to make paperweights, all the way down to simple casein based glues.

Is there a superstrong glue that remains flexible after
hardening? Something with a little give to it?

Source record: 47581

OK, lets try to model the fundamental phenomena we're talking about and try to understand them in terms of simple electrostatic principles.

We start with these assumptions:

1. Vertical antenna of length l
2. Antenna grounded at base
3. Ideal RF current sensor at base (i.e., receiver)
4. Complete absence of electrostatic fields except from #5 below
5. A single negative charge Q that can be moved from infinity to actual contact with the antenna.
6. Electromagnetic effects of a moving charge are not considered; they do exist, of course, so reader beware.

We start by placing the charge Q at infinity so that there is no net charge on the antenna.

As Q is brought near the antenna, its field will cause a redistribution of charges on the antenna. Because the antenna is connected to the earth at its base, a negative charge will flow into the earth from the antenna. This will result in the antenna having a net positive charge Q' such that |Q'|<|Q| (i.e., the closer the charge is to the antenna, the smaller the difference between Q' and Q, and in the limit, they are equal). The negative charge flowing to earth causes a current to be detected by the RF current sensor at the base of the antenna.

As the charge moves closer and ultimately touches the antenna, a movement of exactly -Q into the earth is completed, with the result that the antenna once again has a net charge of zero and from the moment of impact, no further charge redistributions or currents take place.

Note that in this model, the signal we hear is actually generated by the approach of the charge, rather than by its actual physical presence on the antenna. (Consider the effect of insulated wire with this model.)

This is the specific mechanism in the model by which a charge colliding with the antenna causes a quantifiable current in the receiver. Our objective is to get a handle on the waveshape (risetime, peak, etc.) of this current; i.e., can it be detected by a receiver as a noise impulse?

The waveshape of the current pulse will be determined mainly by 1) the magnitude of the charge; 2) the time required for the charge redistribution to propagate through the antenna; and 3) the velocity with which the charge approaches the antenna. We know the magnitude of the charge by construction and assume propagation of the charge redistribution (i.e., we are not talking about charge carrier drift) at the speed of light.

The critical element, of course, is the velocity of the charge as it approaches the antenna. The lower its velocity, the longer the risetime of the induced current pulse. If Q is attached to a snowflake with a velocity of one mile per hour, the current peak will be quite low because the charge redistribution will occur over a relatively long time period.

But if we assume the charge velocity is so high that the other factors establish risetime, we can estimate some of the interesting pulse parameters.

For example, if the antenna is conveniently 1/100 mile long and Q = 1 pC, we get a peak current on the order of 20 uA. If our receiver front end is 50 ohms, that peak current would generate a 1 mV peak voltage pulse with a negligible risetime. (Please check my arithmetic) I think the model shows this to be the highest peak current attainable (under quite unrealistic assumptions).

If the rise-time of the current pulse depends on the particle's velocity, then it is not clear how that pulse's peak amplitude can be increased. I'm not persuaded that resonance is relevant, particularly since so much of the noise we are discussing is very broadband.

We can explore the number of charges that must arrive in some time window to achieve a given combined pulse magnitude at the receiver.

First, however, someone who has not forgotten his math and physics should algebraically relate pulse risetime and peak value to charge velocity. Then we would have an indication of the detectability of a single charge striking an antenna. We could predict the magnitude of the charge and/or the velocity needed to achieve some specified signal level at the input of the receiver. This relationship has not yet been presented and without it, understanding of the possibility of non-coronal precipitation static remains elusive.

Are there other approaches to quantitative demonstrations out there? Does someone have an alternative model of how a charge striking an antenna is translated into a detectable signal?

Have fun!

73,
Chuck

My first experience with p-static was with snow in Norway 1984. The air was very cold and dry before it started snowing it seemed like at first you could hear each flake that hit the wire then finally it just became a rushing sound.

If the neighbourhood had not removed every single tree around, the antenna would not look so stark in it's nested state. We have a lot of those walled estates here in ZS and they seem to attract the same anal residents! The developments here are also devoid of trees. Unfortunately, we don't have a federal law to rely on here, our amateurs have to rely on sneaky antennas only.
Lucily I live in a freehold suburb with plenty of trees. My 55' crank-up also nests at about 20' and is virtually invisible from all roads but one due to the trees around it. Only my immediate neighbours can see it in the nested position, but they still have the trees to get an idea of the proportions so it is not a problem. Trees have more bulk than the antenna and give proportion to it's size.

Maybe that guy should print some info leaflets for the neighbours to inform them that in an emergency situation, that 'eyesore' could be their only communications system and their lifeline to help?

People forget surprisingly quickly that the distance from the top of the (technological) heap to the bottom is an incredibly short distance! One big storm in the right place and infrastructure can crumble and take them back to their medievil walled villages that they appear to be longingly trying to emulate!

What hole comes before a B-Hole?

Merry Christmas to all!

hopefully by 'quad' you mean a 4-band antenna. it could be a bit of a
problem with low bridges and parking garages otherwise. and yes, an antenna
doesn't care what kind of modulation you use, though you may want to
lengthen it a bit if its tuned up near the top of the band for fm repeaters
and such.

This news spot is OLD!

OLD news is NO NEWS.

NEW news is NEWS [so, I'm told].

In the USA there is a federal pre-emption limiting local laws against antennas.

Nicely said, Cecil.

Hope you didn't get the impression I was denying the existence of non-coronal p-static, or attempting to make it go away. But I hope you'll agree that to be detected in a receiver, the static has to have a certain amplitude. We know what that amplitude is and we know the kinds of charges scientists have measured on precipitation as well as typical current densities. What is elusive is how the charges get changed into a detectable signal. Hardly metaphysics, and no more intended to attain Human Understanding than the application of Ohm's law! ;-)

Actually, I was trying to provide a basis or framework within which non-coronal static could be analyzed. Except for the unfortunate paragraph with hypothetical numbers (the sad result of an embarrassing senior moment) the rest seems a reasonable start.

Will you tell me again how we know that non-coronal p-static exists? Without that information we need to say "It is what it is iff it exists", no? ;-)

73,

Chuck

That seems like an odd trade. Perhaps it would be better if you tried to
borrow the money from a friend and pay cash for the quad.

Also curious

Yes, there's a broad range of possible explanations.
One interesting theory is that uncharged particles
rubbing against an uncharged antenna results in a
triboelectric effect that, after contact, leaves the
antenna and particles with opposite charges. You might
call it the relativity theory of charged particles. :-)

> Will you tell me again how we know that non-coronal p-static exists?

By definition, corona requires ionization of the air
which requires a certain current through the air, i.e.
at least a small arc. The question is, can p-static
exist and be heard below the corona threshold?

In 1939, another C. Moore, W9LZX, solved the corona
problem at HCJB in Quito, Ecuador by inventing the
cubical quad antenna. Describing the problem with the
Yagi beam: "Gigantic corona discharges sprang full-
blown from the tips of the driven element and directors,
standing out in mid-air and burning with a wicked hiss
and crackle. The heavy industrial aluminum tubing used
for the elements of the doomed beam glowed with the
heat of the arc and turned incandescent at the tips.
Large molten chunks of aluminum dropped to the ground
as the inexorable fire slowly consumed the antenna. The
corona discharges were so loud and so intense that they
could be seen and heard singing and burning a quarter-
mile away from the station."

So Clarence Moore invented the cubical quad to solve
the corona problem. One must admit that the cubical
quad at least reduced the corona problem by many
magnitudes during transmit. One must also admit that
the corona problem during receive is magnitudes below
the problem during transmit. At some level, the air
ceases to be ionized and corona ceases to exist, by
definition. What can we conclude by applying the
principle of antenna transmit/receive reciprocity?

Comparing the Yagi to the cubical quad is similar to
comparing a single-wire 1/2WL dipole to a full-wave loop.
The ground referenced loop with its rounded corners

certainly reduces the corona threshold level. It is possible that the loop is quieter *because* it is below the corona threshold and the single-wire dipole is not. Can we hear p-static on a full-wave loop? Yes, I have heard it on a clear-sky, low-humidity, windy day in the Arizona desert. Did it occur without ionization of the air? There probably were no points (pun intended) in the system conducive to corona discharge.

Obviously a qualitative argument rather than a quantitative one but possibly valid nonetheless based on the Quito experience.

i have a feeling that what you will find is that the individual charges on
drops, flakes, and dust is too small to be detected by a normal amateur
receiver. However, the electric field that must accompany them is what
generates the corona effects that can be heard. Just think about it, how do
small particles get charged without also generating a larger bulk field?
The effect that charges the particles, be it dry friction from wind on dust,
or freezing and convection in clouds (any cloud, not just those with enough
charge to generate lightning) is not an individual particle effect, it
happens to many, many particles at once which cumulatively create a much
larger electric field than any one of them alone could create. And while
the charge transfer of small drops striking a conductor may not be enough to
stimulate a receiver the corona caused by the accumulated field over the

whole height of the structure can be significant.

4330. Confused how I2 gets coupled to the dipole element

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-26 15:17:15 UTC
From: k1drw <k1drw@comcast.net>
Message-ID: <1167146235.925206.296270@i12g2000cwa.googlegroups.com>
Source record: 47604

I just read one of Cebik's lessons on common mode currents and am looking at a diagram he posts. The diagram shows I1 as the RF current on the center conductor, I2 as RF current on the inside of the braid and I3 as commond mode current on the outside of the braid.

Since I have not seen my query posted anywhere, I am a bit reluctant to ask because the answer is probably very obvious. I hope I don't get chided that I an an Extra, asking a simple, fundamental question. I have studied hard most every day but without the benefit of an electrical/electronics/engineering background, it is going to take the rest of my lifetime to acquire all that I am curious about.

This particular bit of confusion comes from knowing how I attach a PL-259 to the braid of coax. The OUTSIDE surface of the braid fits flush to the PL-259 shell, not the INSIDE surface of the braid where I2 is portrayed to be. Subsequently, the shell of the PL-259 gets coupled to one side of the antenna. I understand the potential for I3. And, I reasoned that the RF current could be initially placed on the inside surface of the braid at the transmitter end of the coax run. But then, back at the antenna end of the coax and PL-259 connector, I only see a dead end for the I2 current. I added a Balun component to my thinking about the issue, but the confusion did not go away.

I just cannot understand how I2 gets coupled to the dipole antenna element since the coax gets coupled at the PL-259 via the outside surface of the braid.

> exist and be heard below the corona threshold?

corona is not an 'arc', an arc is normally between two conductors. corona is a local cascade breakdown in air as electrons are accelerated enough so that when they colide with another molecule of the air they can knock off more electrons. That is why there is a threshold voltage for corona inception, below a given field strength the electrons can't gain enough energy to sustain the breakdown. note that the shape of the conductor is very important in this process also, a blunt smooth surface will produce smaller fields and have a higher inception voltage than a sharp point because the field gets concentrated more around the point and thus requires a lower voltage to start corona breakdown.

> What can we conclude by applying the
> principle of antenna transmit/receive reciprocity?

in this case, nothing. the tx problem was because the rf voltage at the antenna tips was high enough to cause corona on a massive scale. rf voltage on a receiving antenna is miniscule and so can not be the source of corona... this means other sources, not related to rf and the intended use of the structure as an antenna, are the cause.

Wouldn't the whole sky glow at night like the
Northern Lights if the entire dust cloud was
ionizing the air to the corona threshold?

The fair weather current doesn't meet the
corona threshold so how could corona occur
with a rounded full-wave loop under fair
weather conditions?

It is the physics of the coaxial cable that causes I1
and I2 to be equal in magnitude and opposite in phase.
The internal coax fields force that condition. At the
antenna, I1 has only one choice of paths - into the
antenna (if matched). But I2 has two choices - into
the antenna (if matched) or down the outside of the
coax. It will divide at that point according to Ohm's
law most of it taking the path of least impedance.
A choke increases the impedance down the outside of
the coax making the antenna impedance more attractive
to the current.

So the sharp ends of a single-wire dipole would be more
conducive to corona than would a rounded full-wave loop.
Would you say that an antenna without corona is quieter
than an antenna with corona?

Cecil:

Thank you for the quick reply and clear explanation. I now
understand the coupling of rf current from inside the braid to
potentially, depending on impedance, both paths.

Sincere thanks..!

no, the field in the air is below the threshold. it is the concentrated
field around objects that cause the field to exceed the threshold.

>

the fair weather current and the field that drives it is fairly small, not
normally enough to cause corona or we would be hearing it all the time.

of course. we see that here all the time, the top antenna of a stack can be
very noisy with corona, but those lower down on the tower (even though they
are getting hit by the same rain/snow) are quiet.

4344. QSL Cards

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-26 19:09:21 UTC
From: "qslcanadagroups@gmail.com" <qslcanadagroups@gmail.com>
Message-ID: <1167160161.644579.203860@73g2000cwn.googlegroups.com>
Source record: 47618

Name: Kirill
Call: VE3AXC

Merry Christmas and Happy New Year everyone! I will be a subscriber of this forum from now on, so nice meeting everybody!

On this note, please allow me to stray a bit off this forum's topic but my info might still be relevant for some. I myself have been a ham for 8 years; also run a small QSL card printing business (my printishop is located in Toronto, Canada) and have a web site specifically dedicated to that www.qslcanada.com

Reason I would like to post this message on this forum is to let your group know that I have a pretty good group referral discount program.

The idea is quite simple and there is no catch.... For each HAM who is referred by you and who wishes to place an minimum order of 500 cards, you would receive 100 (custom designed) cards of the same type free of charge. The offer is transferable, so if for example you let me know that you don't need any more cards, I will be happy to print additional 100 cards for your friend free of charge (or charge for 100 cards less)

This offer may be ideal for your group or a club you belong to. For example, if you
refer say 3 HAMs who would like to print a minimum 500 cards for themselves, you would receive 300 cards as appreciation for spreading the word about qslcanada
; you could transfer it to someone as a gift ; or each of 3 Hams would only pay
for 400 cards, since each one will get 100 cards free. To sum it up, each of the referral counts as 100 free cards in any shape or form. Pse let me know if you have any questions.

So if bunch of Hams in this group who are into QSLing might be interested to giving someone a free gift or getting a good deal on the next batch, pse let me know. The offer is valid any time in future. www.qslcanada.com has quite a bit of samples, more info and e-ham reviews

PS Have got to mention this, since it did happen before, where some folks took this posting too personally. I just wanted to get this info out there ONE TIME ONLY! Please don't call me any spammer names or hate mail me. I believe this to be a fair group offer any hams by hams enterprise deserves a little exposure to start out with.

I will try to participate in this group from now on, so best 73 to everyone! Happy New Year!

4345. Re: UPDATE: Question about 20-meter monoband vertical (kinda long - antenna gurus welcome)

And thank you for doing much of my work for me! I was planning to put up
such an antenna (20 M ground plane vertical)a few weeks ago. Your post,
and the replies to it, will allow me to erect and tune mine quite a bit
faster.

Thanks for the Xmas present!

4346. [Off Topic] QRA? QCX?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-26 20:51:11 UTC
From: lu6etj <lu6etj@gmail.com>
Message-ID: <1167166270.917806.294900@n51g2000cwc.googlegroups.com>
Source record: 47620

Dear friends: I have a doubt. All of my life (for me and the others
local Hams), QRA = Call sign.

Recently a colleage said me - No... Call sign is QCX - . I don't knew
QCX, but I found it searching the web, Q code listings says:

QRA = The name of my station is...
QCX = My full call sign is...

How old is QCX Q code?

Some stations (no Ham, of course) has a name and a call sign,
broadcasting, coastals , etc.

What do you think about it?

4347. Mechanics of AC current flow - ?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-26 21:04:14 UTC
From: k1drw <k1drw@comcast.net>
Message-ID: <1167167054.718747.134870@i12g2000cwa.googlegroups.com>
Source record: 47621

I have a question about AC Circuitry (as it relates to my antenna system) where I cannot seem to arrive at an answer by reading reference material:

RE: The mechanics of current flow as it relates to a 1/4~ vertical working against ground and separately, in comparison as it relates to the dipole elements.

Is an AC circuit like DC, whereas there must be a ground return path for a "flow" to happen ?

RE Dipole: If yes, then I get confused when thinking about ac current flow relative to a dipole antenna. I can image current flow on the center conductor side, since it seems the current +/- can keep going back and forth from the transceiver to the end of the antenna element (independent of the braid or other half side). But, it is hard to understand how current can go back and forth on the braid side, since it has a path to ground. Seems like on the braid side the current would make its way down to the end of the dipole element and then start back, but go right to the low impedance ground and be gone.

RE: Vertical 1/4~: Again, here I image the ground side of the AC circuit works as described above. But I read references to radials on the ground side "collecting and returning ground currents" and that confuses me. Returning currents to where ?, the current as pushed out on the braid side seems to be where it was supposed to go - to ground.

Do both "legs" of AC current push out on the + and "pull" back on the - , independent of 'ground' ?

I don't have an elec or engnr backgound so if you please to help me understand, please try hard to keep it very basic. I just cannot use math and AC formulas yet.

thanks, and 73, dennis

You can sometimes model an antenna as a set of lumped circuit constants,
but, in actual fact, at least one of these must represent the induced
impedance of the space around it. After all, that's what the antenna
really is--a device to couple energy from the feedline into the space
surrounding the antenna, where it will be lost to radiation.

I realize this isn't going to be that satisfactory an answer. Ground
currents do flow in radials and, because they (theoretically) flow equally

in opposite directions should add up to close to ZERO at the coax braid.

The current at the base of the antenna is high (the only thing keeping it from trying to be a short circuit is the radiation resistance and any resistive losses in the antenna itself). But it need not be matched by any currents elsewhere. It IS "matched" by the induced radiation in free space, though.

4349. Re: RoomCap Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-26 22:09:15 UTC
From: hb9abx@freesurf.ch
Message-ID: <1167170955.348600.234450@h40g2000cwb.googlegroups.com>
Source record: 47623

Let's come back to the subject here, the RoomCap
antenna:

Read what wrote a builder of the antenna:
Paul VE3UNF was answering my question, if his report is a joke, with
the following reply:

I am 60 years old - a retired airline pilot whom has flown all over the
world from small turbo props, right up to the Boeing 747 with over
21,000.0 flying hours.

I have been building antennas off and on now for 15 years at my various
QTH's.
Most of the antennas I have built came from various antenna books which
were mainly stealth type antennas, as
most of my past QTH's were in deed restricted locations. eg . attic
antennas , hidden wire antennas, vertical
antennas off of balconies, short dipoles with traps, the list goes on
and on and I have never been able to make
an antenna that for it's size can perform at all, or as well as, or
outperform this G5RV.

I moved to this location in Florida last year which has an acre and a
half and was able to build this G5RV shortly thereafter.

After reading up on your other antennas and now this antenna. I decided
to build the RoomCap out of curiosity,
-- just to see how well it performed -- in the chance that if it did
give a reasonable account of itself, -- it would be beneficial to all
those hams that I know, that cannot put up a very visible antenna -- as
I remembered how difficult and frustrating it was for me to just get on
the air when I was in Toronto. Well, I built it and I was pleasantly
surprised.

I am going to continue to test this antenna with the G5RV and keep
recording the results irregardless of what anyone says.

If any of these armchair electronic communiction antenna experts want
to keep debunking it with their idea of the laws of physics without
reading all your theories on it--Well so be it, with their ignorance .
They obviously have thousands of dollars invested in their huge beams
and don't care about the poor guys that have to live in deed restricted
areas, who could greatly benefit from this. It would be great if they
could keep an open mind and just start listening to some of the other
reports that will be coming in from other builders.

Like I said before, I have built many many small and large wire
antennas only to have little to mediocre performance. Your antenna just
blew me away with it's performance.

Even though I am not an antenna expert - I know antenna performance
when I see it. I don't care if it defies the laws of physics or you
have come up with some new technological break through --
it bloody works and that's all there is to it .
I really don't care if these so called experts don't believe us. They
can just keep their ignoramist heads stuck in the sand and keep
studying and memorizing the old formulas in their old physics books
till they are blue in the face.

Thanks , -- Paul VE3UNF

>
>
Charges can be accumulated on objects so as to produce a corona
breakdown in many ways. I think this is one of our fundamental starting
points and hopefully, was never in question. The separation of charges
can be accomplished by a variety of techniques, not all well-understood.

A moving cloud of charged particles can induce very large charges into a
grounded conductor. A sufficient concentration of charge at pointed
components of the conductor will produce a corona. The corona plainly
radiates "noise" that is detected by our receivers.

There is less certainty about whether an ungrounded conductor (say, an
unattached wire) can be made to produce a corona via electrostatic
induction. As I wrote in an earlier post in this thread, an ungrounded
conductor cannot be charged by an external field, but the distribution
of charges preexisting on the conductor can be affected by the field,
perhaps causing coronal discharges. I recall writing that uneven
discharges of the positive and negative "ends" of the conductor could
even leave the conductor with a net charge.

Your points are good ones, Dave, and worth keeping in mind.

73,

Chuck

Except it is not DC. If that coax is an odd multiple
of 1/4 wavelengths long, the impedance looking down
the outside of the braid is very, very high. Or if
a choke is installed on the coax, the impedance may
be very high. On a macro scale, RF obeys the rules
of the distributed network model and doesn't respond
like DC.

Source record: 47526

Hi Art

Thanks for taking your time to direct me to some very complex thinking.
But, I'm a rather simple guy who isnt well educated. You apparently expect
a "just regular guy" like me to understand the ccomplex convoluted
theoretical stuff that you write about.
When I did work as an antenna design engineer, years ago, I saw some of my
buddies working on the distribution of energy across apertures in an effort
to shape beams. One of their considerations was to decrease the power to
the elements as they were more distant from the center of the array. I
remember reading that when the power is tapered to provide a distribution
about equivalent to a Gaussian Distribution, the side lobes were minimal.

I really enjoy thinking about real antenna construction projects. but,
when it gets to the Maxwell's Equation kind of analysis, I get lost. I dont
even know what a Vector is.
You may have the wrong impression about me, Art, I'm an old guy who wants
to have fun with antennas. It isnt necessary for you to tell me to "get back
to basics". I dont have interest in the "basics" you refer to.

Is it possible for you to tell us (me) what you are referring to without
referring to Vectors, Gauss's law, Lorentz, "Nagi", and even elementary
calculus? Frankly, Art, you confuse me when you write such scholarly
paragraphs. You and I are so far removed from each other intellectually
that I can never keep up with your texts.

Jerry

> Your points are good ones, Dave, and worth keeping in mind.

floating conductors can definitely create corona. this can be seen in
corona camera pictures of power line insulators and other hardware that is
insulated but still in the high field near a power line. even water drops
on insulators can cause corona in a very strong field. and even if you get
away from power line stuff, a leyden jar has an insulated conductor and it

can obviously be charged, as can aircraft... and if they accumulate enough charge they can cause corona.

4355. Re: Mechanics of AC current flow - ?

You are correct Dave, I did not get much out of your response. Again, my knowledge and experience level is such that I have no idea what a lumped circuit constant is.

What is the current flow as it leaves the transceiver, down each of the two pieces of the coax, in very fundamental terms ? Is there a picture or an animation you can point me to so that I may visualize what is actually happening (assuming no impedance mismatch).

I am having difficulty visualizing the current flow in the circuit. Going beyond that with a description of other activity and components and variables, is not what I am hoping to understand initially. When you say "current at the base of the antenna is high", that still does not help me visualize what is actually, fundamentally happening. Current is flowing, ok, I assume up and down the coax on both conductors (+ and -) and into the antenna elements. Referring back to my original post, for the 1/4~ vertical, current is flowing into the vertical radiator via the coax center conductor and into the ground radials from the inside face of the coax shield. I seem to think that current is also flowing into the radials from other sources, but input from the tail end of the radials. Now what.? Does the current flow go back to the source (the transceiver) and then turn around and combine with more current coming out of the transceiver ? What for ? Why is current flowing into the radials from the transceiver - what purpose ? I can see the purpose of current flowing into the upright vertical element and being radiated. I don't understand the PURPOSE and disposition of current flowing into the radials from either source.

I really want to understand this fundamental concept but seem to have difficulty explaining myself because the responses are not anywhere near what I need explained in a very basic way.

If you would please take another shot at explaining what you think I am asking, it would be appreciated.

Same thing for Cecil. Just a very, very clear, basic explanation of the current flow in both pieces of the coax, into the antenna elements (on the vertical, the antenna 'elements' are the vertical radiator and the ground radials).

sincere thanks for any repsonse.

73, dennis

Hi Art

I hurt my knee, so I have alot of time to spend on this computer right
now. I've been trying to develop skills with Roy's EZNEC. Can you send me
enough data on your concept as I'd need to model it with EZNEC?

I missed the point about the unsatisfactory aspects of a Yagi antenna.

Is there any similarity between your "cluster" and the Wullenweber" (?sp?)
antenna concept?

How are you able to measure the resistive component of an antenna's
terminal impedance then seperate it into two parts? You state that one
resistance is related to current below the surface and the other the current
that flows on the top of the surface.
What frequency band do you do your testing on?? You must have some very
good test equipment.

Is it easy for you to tell me why you want to avoid "reactiveness"?

Tell me how I can model your antenna with EZNEC.

Jerry

> Same thing for Cecil. Just a very, very clear, basic explanation of
> the current flow in both pieces of the coax, into the antenna elements
> (on the vertical, the antenna 'elements' are the vertical radiator and
> the ground radials).

Let's say we have two wires running out to a load.
If we hook a 12 volt battery to those two wires,
DC current flows out to the load through one of
the wires and back to the battery through the
other wire such that the current loop is closed.

With an AC signal, current flows out through one
wire and back through the other for 1/2 cycle.
It then reverses direction in both wires for
the other 1/2 cycle.

Coax is like those two wires. The center conductor
of the coax is one wire and the inside of the
coax braid is the other conductor. When current
is flowing out through the center conductor, it
is flowing back through the braid. 1/2 cycle later
both currents are reversed.

When current is flowing into the vertical antenna
element, an equal amount of current is flowing
out of the radials. 1/2 cycle later, current is
flowing out of the vertical antenna element and
into the radials. Radiation losses from the
antenna and radials make it look like there
might be a 35 ohm resistor attached to the
end of the coax instead of the antenna.

Hi Art

I have to tell you that I am beginning to loose interest in this thread.
I read about "equilibrium" and began to wonder what that meant in a
discussion about a cluster of radiators. Then, when you explained
equilibrium in terms of balloons, ball bearings and sweat, I began to
wonder if you are pulling my leg.

Now, I really feel like a guy who went snipe hunting and got left out
alone all night. You are playing with me, aren't you?? I asked for data
and dimensions so I could work *with* you to better understand your
"Cluster"
You reply to my request for information with sentences like this --

>Sound simple but there are difficulties, when you weaken the enclosing
> force it does produce a major hole for directive purposes however at
> the same time multiple fissures open in other areas which provides a
> leakage trail for the swerling innards such that radiative energy on a
> smaller scale still escaopes to form radiation in other areas than the
> forward direction envisioned.

If your goal is to show that I am too stupid to know when I am being
tricked, you won.

Jerry

Hello Cecil:

Once again, I extend thanks to you for your 'elmering'. I understood your response completely.

RE: the vertical configuration: It seems then, that the 2nd half of the cycle on the vertical (where the current flow is coming out of the vertical element and into the radials) is practically worthless in terms of radiating signal into the 'ether'. At first thought it would appear that there is more efficiency with an elevated 1/4~ vertical element and using elevated radials and or counterpoise -vs- ground radials.

Cecil, I can only offer thanks, but it is many thanks...!

I'm not sure some of the suggested compounds would work.

I assume the OP is interested in maintaining a very high dielectric constant -- at least, that's a common reason for using barium titanate. The presence of even tiny gaps between particles will drastically lower the overall dielectric constant, for the same basic reason (substituting electric for magnetic fields) that an air gap in a magnetic path consisting of otherwise high permeability material will drastically lower the overall permeability. So what's required is a compound that allows the barium titanate particles to contact each other. I don't know what kind of binder might do this, but it seems to me it would have to be something that shrinks as it dries or cures, like conductive epoxy binder. Conductive epoxy binder pulls the gold or silver particles together when it cures to get good electrical conductivity.

I thought that capacitors and the like which use barium titanate were fired into a homogeneous ceramic.

> make its way down to the end of the dipole element and then start back,
> but go right to the low impedance ground and be gone.

Current flows into one half the antenna, which causes it to create a field. The field strikes the other half of the dipole, inducing a current in it. The current into one half the dipole has to equal, at every instant, the current out of the other half. The path is through the air, with the coupling mechanism being the electric and magnetic fields. If this is hard to swallow, think a bit about how current flows "through" a capacitor or transformer.

> RE: Vertical 1/4~: Again, here I image the ground side of the AC
> circuit works as described above. But I read references to radials on
> the ground side "collecting and returning ground currents" and that
> confuses me. Returning currents to where ?, the current as pushed out
> on the braid side seems to be where it was supposed to go - to ground.

The field created by the current in the vertical couples to the ground, and induces a current in it. This current flows in the braid. The current into the vertical has to, at every instant, equal the current flowing out of the ground. The radials lower the resistance of the current path through the ground.

> Do both "legs" of AC current push out on the + and "pull" back on the -
> , independent of 'ground' ?

Sorry, I don't know what a current "leg" is.

Don't feel bad, Jerry. Quite a few of us who do have an engineering education and a lot of experience with antennas don't understand Art's postings either.

OK Art, if you say that you arent actually "pulling my leg", perhaps *I* can help *you*. It doesnt require computer literacy to be able to use Roy's EZNEC. I am perhaps the least computer savy reader of this News Group. But, I am beginning to learn things with this antenna modeling program. I suggest to you that you will benefit so much as the result of buying Roy's program that you will thank me for having suggested it to you. I dont consider it appropriate to use the free EZNEC program. The "paid for" version has somewhat improved capabilities. And the cost of that program is far less than the excellent test equipment you now have. It just seems Right to buy from Roy since he took so much time to make such a capable tool for us.

Go to Roy and buy the program best suited for analyzing your concept. It is actually fun to see that program at work. You wont regret having EZNEC in your "tool box". Value per dollar, there is no tool available to the antenna designer that is better than EZNEC.

Try it, you'll like it.
Jerry

Hi Art

It really surprises me to earn that you know about Roy's program and then dismiss it. I thought you had explained that you werent able to use it to the satisfaction of some other Antenna guys.

I included a question within your post where I ask if you really want a computer modeling progran to tell you where to locate elements.

Is it true that there is a computer modeling program that is superior (for HAM/Amateur use) to EZNEC??? I'll go look for METLAB on the Internet.

Jerry

Art, do you really mean what you seem to have said??? Do you want a computer modeling program that *tells you* where to locate elements??

In other words I need a
> program that helps me not just shrug its shoulders emphasising the
> dumbness of the program. If you really want to get into modelling then

Oh nuts, Art, I cant even read properly. I thought you told me that you
werent computer literate and that you werent able to define the antenna you
are proposing to be a "CLUSTER". I can only apologize for being so dumb
that I cant seem to make sense out of your posts. I'll leave you to
discuss your "CLUSTER" with those bright guys who can read and understand
your text.

You seem to have implied that you think ""EZNEC deals with parallel
elements probably must be in line"". It isnt true that EZNEC is limited to
either "parallel" elements nor "in line" elements.

Obviously I am far too easily satisfied with computer programs for
modeling antennas. I really like EZNEC and found it really easy to learn
how to navigate in it. Art, I could never discuss antenna theory or
operation with you are far too wise and knowledgeable for me.

Do you mind my asking what kind of profession you are employed in??

Jerry

Nice fantasy you have there. Did you come up with it yourself, or did
you have to steal it?

>

Hi Dave,

A leyden jar is, of course, a capacitor. It is charged by grounding the outside, applying a charge to the inside conductor, and then removing the ground. Hope I didn't cause anyone to suspect that a capacitor could not be charged that way.

Recall that in electrostatic induction, we always ground the conductor, bring a field near it, and then remove the ground connection. A net charge then remains on the conductor even after the inducing field is moved away.

Aircraft can be and are regularly charged by the triboelectric effect. The issue I raised is whether they can be given a net charge by immersion in an electric field.

I also tried to explain that it is possible for a floating conductor to produce a coronal discharge without that conductor having a net charge, and followed with the suggestion that the act of producing a differential coronal discharge might itself result in a net charge on the conductor, but the corona can be produced by the field even when the conductor is not charged. Your power line example may be a good example of coronal discharge of a floating conductor in a strong field, but we probably don't know if it ever had a net charge on it due to the field.

Hope this clarifies my thoughts a little. ;-)

73,

Chuck

Dennis, you got the simplified version. When current is flowing into the antenna, electrons are flowing out of the antenna. When current is flowing out of the antenna, electrons are flowing into the antenna. Either way the electrons are flowing, they are being accelerated for part of the cycle. So RF radiation (photon generation) occurs no matter which way the electrons are flowing.

In addition, the vertical is a standing wave antenna. It actually has RF waves moving both directions at the same time. There's the forward wave moving toward the top of the antenna and the reflected wave moving from the top back toward the feedpoint. The SWR on a 1/2 wavelength dipole is in the ballpark of 20:1.

For an antenna to be close to 100% efficient, it must radiate equally during both half cycles.

You can blame Ben Franklin for current flowing the opposite direction from the electron flow. He didn't know electrons carried a negative charge. So by definition, current flows from plus to minus but electrons actually flow from minus to plus. In addition, RF current flow is associated with the RF electromagnetic wave (photons) , not with the electrons which move much slower than the speed of light.

Cecil:

I was unaware that anyone had proved the "absolute" existence of
photons, beyond mathematical formula and "interpreted" experiments ...

This:
The "discovery" of the photon, based on the interpretation of
experimental results that otherwise seemed mysterious, was made in a
scientific paper by Albert Einstein in 1905.

from here:
http://zebu.uoregon.edu/~soper/Light/photons.html

This:
Photon was a live action series based on the infrared tag game popular in the 1980s. The series took place on Earth and in space on various worlds and involved a young human teen named Christopher Jarvis who is a champion player of Photon. He receives a mysterious message one day while playing and is transported to the ship of Mother One, the leader of the Federation of Light a galactic amalgam of beings dedicated to playing Photon and the power of good over evil. ...
en.wikipedia.org/wiki/Photon_(TV_series)

A Google search for "existence of photons" turned up
more than one million entries. The existence of photons
has been proved to my satisfaction. They have been
captured on sub-atomic particle plots and have been
proved to obey Planck's quantum principle. A single
photon has been shown to interfere with itself during
double slit experiments. A photon certainly exists but
I am not "absolutely" certain of exactly what it really
is as photons possess the particle-wave duality. However,
so do electrons and massive 60 atom carbon Buckyballs.
So how can 60 carbon atoms go through two slots at the
same time?

Here's one of the photon experiments.

Cecil, OM:

I agree, there is something which surely "acts" much like a "real" photon should. Mostly, I am just joshing 'ya.

But, we may have to revise our present theory about photons in the future, at some point.

However, there is one photon which has been all over the house here, actually, it CAN seem to be in two places at once! I have termed the discovery of this "new photon" the "Fly-Photon" and have began swatting at it!

Well, Art, You and I are probably about the same age. I'm 75, so I was too young to fight in WWII. Also like you I spent time in the service. I spent 4 wonderful years as a radio operator and repairman in the USAF during the Korean conflict. I considered that experience to be extremely rewarding. I also got an engineering degree and worked as an antenna design engineer for 15 years, but got layed off in 1969 because I wasnt quite good enough at it to be considered essential.

If you ever get around to sketching the approximate details of your "cluster" of radiators, send it to me. I'll try to model it. I'm OK at reading sketches, but not nearly as good at reading and understanding your written text descriptions. Maybe I should have studied more when I was young. Then, maybe, I could fathom your text.

Jerry

We, the human race, may have to revise our present
theories about *everything* in the future. :-) That
is, unless the patent office guy was right - you
know, the one who said, around the end of the 19th
century, that everything had already been invented.

Hey, all he did was spawn a "Everything Has Already Been Discovered Society", and of course the famous "Everything IS Already Known Society." But, my all time favorites are the, "Don't Challenge Present Thinking and Theory Society" and, "If Einstein Said It, It Must Be True Society."

I end up having discourse with a number of these groups members here--usually the latter. <serious look>

Alas, I was born too late, all the good theories were taken.

Regards,
JS

I just tuned into this News Group to find some and not all ham's like to speak better of there self's than they act.
I thought that was why people became Ham radio Operators and had gotten away from C.B. God I hate that C.B. I get sick thinking about it. I've been a S S B Radio Operator for a long time. Yes I prefer to that think that there are Three types of Radio. No need to go there and get my but kicked by the know it's on here. It has been said so many times no matter what the Hobby. There is always someone out there trying to take the fun out of anything good. And I just seen some of them here. I have been wanting to become a Ham operator for I'll bet at least 35 or 40 years. The code has always stopped me. And the But head's and those with attitude Overly goody two shoes crowds. I have a learning disorder. It does not make me retarded, it simply means that I learn better for me in a hands on manner. Code is plainly just to much for people like me.
Now My point to all this is once again I'm hanging on a tread, I just don't know why I would want to go into Ham and put up with these too kinds people when I'm already doing it and I don't like it any better now. The only plus that I can see at this point is more Frequencies. Ham was a Hobby that was intended to be HELPFUL IN ALL OF IT'S ASPECTS.....
Now look what it's coming to. Some don't want the no Code, other's do and if they remove the code I'm afraid it will let in all the nut's .Well my friends you folks all ready have them. And in the mean time your keeping Good honest people out. Honest people aren't Born..... It takes a Very strong willingness now days to be one.. Ask me it's hard and we don't always win so . Your art form, your hobby no matter what your calling it today is steadily going by the way side. And some of you are so caught up in yourselves that you just can't see it. Some of you are the Sign of your time. I'll Bet there are a lot of old timer's just shaking in there Graves at the way you have been presenting the hobby that they helped to grow. Kind people used to run the Ham band's and there are still some out there are you one of them. Or do you just think you are Action's speak louder and farther then the Air waves. I'm not even a Hammer and I can see that..... I'll be

listening......

Amen, Cecil!

Anyone who has lived in central Texas and is an active ham has
experienced all sorts of extraordinary noises....corona discharges,
precipitation static, and others.... which can be experienced on a
clear day, cloudy day, rainy day, dusty day....though I would hasten
to add that the most dramatic noise performances occurred with an
approaching weather front of some kind and *are* probably corona
discharges. Other noises that I experienced while trying to work DX
were not so easily identifiable as corona.

I haven't experienced the same noises here in Virginia. Here, I get
little in the way of warning, other than normal crashes of static,
before hearing a loud *bang* of thunder indicating that I should
disconnect aerials and vacate the shack!.

One other empirical data point...all of the above mentioned noises
were *dramatically* reduced when switching from plumbers-delight, yagi
antennas to closed loop, cubical quads. Always. Despite the fact
that many have insisted that quads aren't "quieter" than yagis, it's
my story and I'm sticking to it. I use yagis now. If I lived in
Texas, I would probably be using quads again.

Hi all,

I'm looking to purchase an dual-polarized antenna that operates at 2.4Ghz. In particular its necessary that the phase centers of each of the elements be close to spatially identical. So I guess something like a patch antenna with the elements making an X pattern and centerfed feeds. Any suggestions where to order such an antenna? I've purchased most my antennas from hyperlink but don't carry this sort of antenna. Thanks for any suggestions,

Kev

"It's not nice to misrepresent Mother Nature."
http://www.lowgenius.net/kookway.htm
TEH WAY OF THE K00K
Never learn from your mistakes.
Always practice your mistakes; you may get them right.
Always pick on those smarter and tougher than you.
Always believe that only you know the TRVTH.
Never allow logic or reason get in the way of a good k00k.
When being overwhelmed by logic and reason: k00ksuit!
If you are going to be wrong, do it at the top of your lungs.
When caught in a lie: LIE!
When in doubt: Order the Crab Won Ton
Plagiarism is your friend. Use it.
Whenever contradicted; morph, start calling people names, and make false accusations. Include the children of your target in your allegations, even if they don't have any.
(06-Jun-05) When nobody else will listen, post to your own fan group.
(06-Jun-05) Obviously, since you have your own fan group, this must mean that you have fans. Post prolifically to your fan group - you wouldn't want to disappoint them!
(10-May-2005)Everyone reads usenet. Approval here means approval everywhere.
Post numerous blank posts, or posts containing only a message id.
Post numerous copy&paste web articles from crackerpot websites.
Never forget to call kookologists "k00ks."
If there are several, call them "sockpuppets" too
When all else fails, accuse various and sundry kookologists of e-mailing viruses to you. This is a sure-fire method of garnering sympathy and ensuring that the General Public will always see things your way. An especially effective sub-strategy here is to accuse them of infecting you with the 'Sasser' worm via e-mail.
Quote notorious scientists or writers - it makes it look as if they approve the drivel you are writing!
(9-Jul-05) Anytime your computer is infected with a virus, bogged down by spyware, attacked over your internet connection, or otherwise suffers from preventable problems, government agencies are responsible and are trying to silence you and are monitoring your computer files.
Ignore all traffic signs and feel free to trespass, you don't have to obey any rules.
Scare your enemies with lawsuits, police escorts and whines.
Always back up your empty (albeit noisy) threats with phony LARTs, false police reports, and harassing letters to the FBI and other gubbermint agencies.
Be vigilant in your redundancy. The more you repeat yourself, the more likely others will believe you!
If you can't find anyone as crazy as yourself to support you in the flamewars you start with the normal population, create sock puppets and use anonymous remailers that shamelessly hang on every word you write.
(17-Mar-05) When dealing with law enforcement, remember that it is they who have the problem, not you. Be sure to inform them of this at every

available opportunity, as they will surely appreciate your constructive criticism. Be sure to make them aware that YOU KNOW YOUR RIGHTS! ("The cops like that, when people know their rights. That way they don't have to read them to you on the way to the station." - George Carlin)
The more your fake personalities adulate you, the more respect you'll get!
When confronted with a reality that you don't like: Announce loudly that you are departing, never to return as long as there's an Internet. Come back in three or four days and claim you were drunk, hacked, abducted by alience, or forged. Alternately you can just not even mention your prior departure, and if anyone asks you about it, either ignore them or respond with something along the lines of "YOUR NOT THE BOSS OF ME! *PLONK*!" People really know you mean business then.
Always remain clueproof.
(20-Mar-05) Anyone who does not believe that you are the reincarnation of [$DEITY_OR_PROPHET] is obviously an infidel lacking in faith whose soul in in peril of everlasting damnation.
When responding to one line challenges, post paragraphs of rants and screed in response.
Incoherency is not a roadblock to poasting.
Neither is illiteracy.
Delusions poasted often enough become fact.
Claim you will destroy <insert newsfroup> for attacking you.
When spnaked, send cmsg for Fanboi newsfroup(s).
Find your Lame, Use your Lame, Be your Lame!
Post Edit when the TRVTH hurts.
Always sneck the offending newsfroups.
Always poast pictures of yourself so you can be admired in all your k00ky glory.
Always accuse others of the very acts you are guilty of.
Post lots of boasts about your high IQ and incredible talents.
(20-Mar-05) If you repeat a lie often enough, it becomes the truth. Anybody who fails to understand this is engaged in a deliberate campaign of misinformation and character assassination.
Always <plonk> somebody just before replying the plonkee!
The k00k considers itself the most intelligent person in any conversation, possibly on the planet. Other people are benighted and ignorant, and have been waiting their whole lives for the k00k to rescue them from intellectual darkness.
Write a self-published book and claim it a success. Bonus points for comparing it to "Mein Kampf" and/or the Bible.
Declare yourself equal to a deity of your choice.
Claim that you've come from other planets.
Claim thousands of past lives.
Frothing complaints carry far more weight when you send them from "legal@" some domain.
Nothing strikes terror into the hearts of your detractors more than telling them that you're archiving their messages for possible use in the future.
Never forget that everyone else posting to Usenet is a paid

disinformation agent looking to discredit you.
Usenet is governed by US law. If a poster in Romania killfiles you, he's obviously violating your 1st Amendment rights and can be sued.
Every news admin in the world hangs out in NANAU, and they're just dying to nuke the account of that meanyhead who just called you "fucknozzle". Drop 'em a line - that's what they're there for, after all.
AUK will be closed down. Just you wait and see.
They've nuked hundreds of accounts in the name of free speech and *yours* will be next.
The k00k will, without any trace of irony, lie, manipulate, impersonate, censor, and declare themselves powerful in ways ranging from the ability to have an account shut down to being God Herself, in order to convince people that they are not liars, manipulators, censors, or insane.
Abuse women while telling how many hundreds you've loved. Nevermind that you're one ugly motherfucker and that there were 30,000 femininas that thought you were a scumbag with bad teeth.
Remember that your ko0ky klaims are 'facts', and that 'facts' do not require proof.
Do not neglect to poast your responses to forums that the originator doesn't read. This will make the people in that forum very impressed with how you tear him to shreds without him being able to respond. They like it even better if you are off-topic for that forum.
Keep in mind that lack of evidence supporting your konspiracy theory actually _is_ evidence, of how effective the konspiracy is in hiding.
(06-Oct-05) When spanked, always retreat to the safety of the Ad Hominem.
(04-Aug-2005) When spanked mercilessly for days on end, proving with each poast just what an illiterate and ignorant fool you are, ALWAYS claim ownership of [person(s),froup(s)]. This works on so many levels. It inspires dread in your opponents that they will no longer be able to poast in their home froup and that they will eventually have to pay rent, to name just two.
Any problems with your poasts are the fault of the konspirators, who are trying to stop you from preventing the extinction of humanity.
Konspiracies that are able to subvert whole governments are always unable to silence konspiracy ko0ks.
The entire United States government is willing to spend millions of dollars for the sole purpose of harassing you.
Hollywood is making movies based on your personal life.
Do not consult psychiatrists or other mental health professionals. They are part of the konspiracy, and will sedate you and lock you away and keep you drugged if you tell them the truth.
Numerology and Astrology are respectable sciences and are useful for proving your case.
Everyone is Tim Hill, or David Green, or...
There is a fine line between trolling and kookery. Find that line and cross it repeatedly. When you are killfiled and/or LARTed for net.abuse as a result, claim victory. If you lose multiple accounts, this merely proves that you are indeed a world-class troll, with a black-belt in manipulation.

If you respond to every post someone else makes, they're obsessed. If they respond to less than 1% of your posts, they're even more obsessed.
Publishing people's real names, addresses, and phone numbers when there's no other way for you to come out of a flamewar with any dignity is cool, and proves that you are a master of secret internet information stores, and absolutely not to be fucked with.
Everyone is out to get you. You can put a stop to this by telling everyone that they're out to get you at every available opportunity.
You are the only sane one.
Those that give you a hard time about morally bankrupt things you yourself admit to are just persecutioners of the new inquisition.
Yelling in all caps and cursing at your detractors is debate. Your detractors laughing at you with sarcastic remarks is obvious anger and jealousy.
If doing something results in the loss of your account, legal hassles, or blunt trauma injury, do it again. It always works better the second time.
Asterisks, lots and lots of Asterisks.
Poking holes in kookscreed is stalking, and is a felony.
K00ks LOVE to "connect the dots". They are, of course, dots that only the k00k can see.
"They laughed at Einstein, too!"

SAN FRANCISCO: It may be the ultimate SOS.

Morse Code is in distress.
.....
.....
While the decision had been expected, some ham radio operators fear that
their exclusive club has been opened to the unwashed masses
- and that the very survival of Morse Code is in question.
.....
The demise of the Morse requirement, however, could be a boon for ham radio
itself. After the FCC decision, demand for information
about radio licenses surged from about 200 in a typical weekend to about
500, according to the American Radio Relay League, an
organization representing ham radio operators.
.....
"It's part of the dumbing down of America," said Nancy Kott, editor of World
Radio magazine and a field representative for the
Centers for Disease of Control and Prevention in Metamora, Michigan. "We
live in a society today that wants something for nothing."

A female in a mostly male radio world, Kott is one of about 660,000 licensed
ham operators in the United States and is the U.S.
leader of Fists CW Club, an organization that calls itself the International
Morse Preservation Society.

... So true, Ms. Kott...

Sorry for this delayed reply...

The question about harmonics (as distinct from IMD) from VSWR meters came up in my Radcom column in 1997.

The following text is based on what I could find out at the time. I can't reproduce the schematic of an old-style VSWR meter here (called "Fig 39" in the original article) but it is similar to the schematic in the Wikipedia article. R2 is the resistor that terminates the sampling line, with the diode detector at the opposite end of the line. RV1 is the "sensitivity" pot between the diode detector and the moving-coil meter.

****

Q: IN MY HF STATION, should I put the lowpass filter between my in-line VSWR meter and the antenna, or between the transmitter and the VSWR meter? Local club members are split on the issue!

A: IT MATTERS LESS than some people think. There is an old, old story that the rectifier diodes in the VSWR meter cause harmonics, and that therefore the lowpass filter should come after the VSWR meter to prevent these harmonics from reaching the antenna and being radiated. That may once have been true, but it required some special conditions that rarely apply any more.

The older style of HF VSWR meter used coupled sampling lines, parallel to the main conductor of the coaxial cable (Fig 39). The coupling between the main line and the two sampling lines increases with

frequency, so a sensor designed to cover all HF bands would be very strongly coupled on 21 and 28MHz - all the more so if the moving-coil meter was not very sensitive and the coupling had to be increased even more. On the higher HF bands, the sensitivity control RV1 would be turned down so as not to 'pin' the meter, but there is no doubt that the diodes were being driven quite hard. Because the coupling increases with frequency, any harmonics generated in the sampling lines would be coupled even more effectively back into the main line. Under these circumstances, interference to Band 1 TV on the second or third harmonic would be quite possible.

Modern HF VSWR meters are quite different. They use a transformer coupling system that is essentially independent of frequency, and in most instruments the moving-coil meters are also more sensitive than in days of old [1]. Therefore the diodes are driven nothing like so hard, and there is much less likelihood of significant harmonic generation. Even with the older-type of VSWR meter, harmonic generation was by no means universal. G3RZP has grossly overdriven his old 'Labgear' meter until the terminating resistor R1 bubbled hot wax, but still found no sign of harmonics above -70dB with respect to the main carrier.

It therefore seems that, especially in modern times, the EMC hazards of connecting a VSWR meter straight to the antenna are over-rated.

****

[1] Inside a Directional Wattmeter: 'In Practice September 2002 (written 5 years later than the above):
http://www.ifwtech.co.uk/g3sek/in-prac/best-of.htm#bruene

The "harmonics" story is an old one, but the accusation that VSWR meters also contribute significant IMD is new to me. However, since we don't observe significant levels of harmonics generated by the diode detectors in modern VSWR meters, it's also very unlikely that we would observe significant levels of IMD since the two processes are very closely related.

As Owen and others have remarked, the "IMD" story seems to be nothing more than a new twist on an old (but persistent) piece of ham folklore.

To bad it's nearly 10 years out of date and wholly unaware of the
vector miracle of optimized Gaussian bundles, or novel definitions of
length efficiency.

Aside from that, I would think it provides a super-saturated solution
of inspiration. Just dip in a string and make your own rock candy
linear loaded radiator. Add drops of food coloring and it makes a
great Christmas tree decoration.

Hi Michael,

I've recently fabricated a 35' tilt-over mast from aluminum pipe but it sounds like you're locked into using a push-up mast. Rohn used to make push-up telescoping masts I see that now, Channelmaster (http://www.channelmaster.com/) is making them. They produce 30, 40, and 50' models in both standard and heavy-duty versions: http://www.pctinternational.com/channelmaster/mounaccess.html. Lowes handles Channelmaster.

Ideally, you'd want to get the antenna up at least a quarter-wavelength. However, at 80m as an example, this is some 60' -- which will be problematic with a push-up mast. Get the antenna up as high as you can manage. You'll some assistance to erect the taller masts, and then you have a mast that is only electro-galvanized steel -- which will rust out and then become an even bigger problem to maintain or disassemble. At the very least, replace the hardware with stainless steel (and use antiseize compound on the threads). For antenna erection/mainenance, hang a good weatherproof pulley on the top and use UV- and rot-resistant rope. McMaster-Carr (http://www.mcmaster.com/) is a good source for these items.

Perhaps the Amateur could get rid of his unattractive antenna if
the neighborhood would agree to purge itself of other eyesores - such as
the adipose and unnatractive women complaining about the antenna.

> Radio magazine

In the R&O, the FCC observed that there was no connection between morse code knowledge and compliance with the rules. The old 14.313 disaster was back in the days of 13 WPM and above coded hams. And VHF didn't turn into a CB mess since no code technician licenses started. And HF didn't get worse with 5WPM generals and extras. So as far as the FCC is concerned, they decided that there was no regulatory point in keeping element 1 in the tests. And the FCC isn't in the business of handing out merit badges. The whole point in requiring license testing is to be sure that people are at least aware of the responsibilities involved with transmitting RF into the radio spectra, that we do it in such a way that doesn't trash the spectrum for other users, ham and others. We then get permission to build, modify and so on transmitting equipment if we want to. CBers or FRSers are not supposed to do that.

As for newbies, virtually all new hams want to be accepted into our world, and will learn and adjust their operating habits as needed to be accepted. This has been true since day one, and aside from a few fools saying things like "No kids, no lids, and no space cadets" everyone knows what it was like to be a newbie.

Wow, it's taken Rockwell nearly forty years to discover this technology. This is obviously only a minor modification of the Turbo-Encabulator, described in detail as early as 1967. I noticed that many of exactly the same basic principles are used in the "new" device. Here's where I first heard of this technology:

From Q POINT, the 9th Aerospace Defense Division newsletter, March 1967

Something for the Technically-Minded

(Our more technically-minded readers have occasionally criticized Q POINT for carrying what they consider less than significant articles. Because of this criticism, we offer the following article on the development of the Turbo-Encabulator. Frankly, it is a little deep for us, but we hope you find it something of value. - Ed.)

For a number of years now, work has been proceeding in order to bring perfection to the crudely conceived idea of a machine that would not only supply inverse reactive current for use in unilateral phase detractors, but would also be capable of automatically synchronizing cardinal grammeters.

Such a machine is the "Turbo-Encabulator".

Basically, the only new principle involved is that instead of power being generated by the relative motion of conductors and fluxes, it is produced by the modial interaction of magnetoreluctance and capacitive directance.

The original machine had a base-plate of prefabulated amulite, surmounted by a malleable logarithic casing in such a way that the two spurving bearings were in a direct line with the pentametric fan. The latter consisted simply of six hydrocoptic marzelvanes, so fitted to the ambifacient lunar waneshaft that side fumbling was effectively prevented. The main winding was of the normal lotus-o-delta type placed in panendermic semi-boloid slots in the stator, every seventh conductor being connected by a non-reversible tremie pipe to the differential girdle-spring on the up end of the granmeters.

Forty-one manestically spaced grouting brushes were arranged to feed into the rotor slip-stream a mixture of high s-value phenylhydrobenzamine and five percent reminative tetraliodonexamine. Both of these liquids have specific pericosities given by P-2.5c. n 6.7 where "n" is the diathetical evolute of retrograde temperature phase disposition and "c" is Cholmondeley's annular grillage coefficient. Initially, "n" was measured with the aid of a metapolar refractive pilfrometer (for a description of the ingenious instrument, see "L. E.

Elektrotechnistratischs-Donnerblitze," Vol III), but up to the present date nothing has been found to equal the trancendental hopper dadoscope. (See "Proceedings of the Peruvian Academy of Skatalogical Sciences," June 1914.)

Electrical engineers will appreciate the difficulty of nubbing together a regurgitative purwell and a suporamitive wennelsprocket. Indeed, this proved to be a stumbling block to further development until, in 1942, it was found that the use of anhydrous nagling pins enabled a kryptonastic bolling shim to be tandered.

Undoubtedly, the turbo-encabulator has now reached a very high level of technical development. It has been successfully used for operating nofer trunnions. In addition, whenever a barescent skor motion is required, it may be employed in conjunction with a drawn reciprocating dingle arm to reduce sinusoidal depleneration.

The 30M band is too narrow to support much SSB usage and is therefore not very suitable for that mode. It is much more suitable for narrow modes such as CW and psk31.

Thank you for your patronizing comment about the USA finally doing the right thing by ending morse code. May I return your sentiment by observing that I am "glad" that South Africa finally did the right thing when you recently ended Apartheid (about 250 years after the US ended slavery).

Hi Steve,

Tried to email you but it bounced. Here's my reply I wrote:

Hi Steve,

You're welcome! I'm having a blast with the new antenna - I've only used trap verticals in the past, and they are SO sharp that you have to pick a band segment and live with high SWR elsewhere forever. Since I run QRP on 20 a lot, I wanted it to be as efficient as possible. I have been tweaking some more and now the SWR at 14.025 is not measurable on my meter, and only 1.3:1 at the far end of SSB! Using my MFJ-259 antenna meter, I was able to tweak the down-angle of the radials for a precise 52 ohm match at the transmitter. So now I think every microwatt possible will make it into the air!

I was very surprised to find that I could make up for the slightly short vertical element (about 2 inches off I'm guessing) by tuning the 4 radials.

It took a LOT more wire than I expected - over a foot on each. But the MFJ meter says it's dead-on resonant at 14.025 at 52 Ohms, so obviously tuning the radials is very important. The vertical element was a BEAR to get up so I was dreading getting it back down - it's copper water pipe and I had to fish it around tree branches to get it in the clear. And the weight vs. leverage (only 25 pounds 'dead weight') made it seem like it weighed at least 100 pounds!

It's only about 12-14 feet up (haven't measured) and the radials get close to the ground (5 feet or so) with the proper 'droop' - but it clearly runs circles around my 200' random wire with tuner - most signals are

2-3 S-Units better on the vertical (some signals though still come in better on the wire, so I have both tuned for where I'm operating in case I need to switch).

Now to build a high-performance (!!) inverted vee for 40-meter QRP work.

Good luck in your project - if I can help in any way, drop me an email.

If you want pix or diagrams of how I built mine, just let me know.

My 2 cents on this....
Code has been on it's way out for a long time. With all the new modes it is hard to require code and not the others.
Being a new ham myself, I found the 5wpm easy, to tell the truth 5wpm is harder than 15wpm to me. Sometimes you can go too slow...
One thing that I have a problem with in the general written test is the lack of proper operating procedures. I had no Elmer's for HF so the only way I learned was by listening and making a few embarrassing mistakes that I was corrected on with no lack of teasing. I wont say what was said but lets say there is a wide gap between 2 meters and HF.

BTW I can repair my TS-400s and I run all my rigs off of solar power and battery storage. I am not an idiot but have found that the more I learn about ham radio, the more questions I have.
I just wish that there were more people out there like all of you, that takes the time to help out the newbie's like me. I am a 45 year old newbie.
One more note..I was able to help out the EOC in Gulfport Mississippi, after hurricane Katrina shortly after getting my technicians license. I was down there for work and donated my spare 2m rig. So I guess I am proof that even a newbie can help out when it counts.

Search for "polarization diversity antenna". You should find some
such as:
<http://www.hyperlinktech.com/web/re11dp.php>
There are plenty of dual polarization and circular polarized antennas,
but most have a single coaxial feed line.

I don't know of anyone doing dual crossed dipoles (or colinears) with
a common phase center. The design of the coax to dipole transition
would be rather messy. Two baluns in close proximity would be
necessary, and they are certain to couple to each other.

The requirement for a common phase center is rather odd. I can only
speculate that you're trying to feed a dish reflector with this
antenna. If this is the case, there are better ways to do diversity
polarization such as a "can" type of feed, with two feeds positioned
90 degrees apart.

Some clue as to what you are trying to accomplish would be helpful.

At what point is the potential Ham Dumb and wanting something for
nothing?

Was it when they lowered the requirement to 5 wpm for all license
classes? Speaking of 5wpm, were all Novices dumb and looking for
something for nothing? And were Generals and advanced just dumb enough,
and just looking for something for almost nothing?

I'm just about at the point of thinking that Morse CW use *will*
increase after the test requirement goes away.

I wonder what type of antennas the new dumb hams will use - just to
bring this on topic, since it's crossposted to an rraa.

hhac:

Implementing logic, I'd venture a guess the CDC has an outreach program in SF. SF has a major segment of the queer population in America, the aids disease is out of hand.

Although aids is insignificant when compared to cancers death toll and there IS a cure for aids, tons of money gets thrown at it while cancer goes wanting.

If I was forced to venture a guess further, I'd almost bet Ms. Kott is a lesbian (that is just a personal opinion and guess!) I am almost always leery of lesbians, too often we end up in competition over the same women, and they get angry if they lose!

And, I'd suspect (I never have checked) the amount of male licensees must out number female licensees 10:1 or better, heck it could be 100:1; If it is as I suspect, Ms. Kott is a lesbian, what better hobby to find if you are into male bashing? (she'd just love to make a bunch of "dumbed down hams" out of the amateur population)

4430. Welding Rod J-Pole Possible?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-28 10:03:31 UTC
From: Chuck James <c456james@sbcglobal.net>
Message-ID: <TDMkh.7702$yC5.4056@newssvr27.news.prodigy.net>
Source record: 47504

I know I could just go buy a mag-mount mobile antenna, but would it be possible or even practical to build a J-pole type or vertical (without long radials) antenna for 2m/70cm, out of welding rod, which could be small enough to be easily portable and used inside different rooms? Our local RACES is trying to set up a volunteer communications network inside several different city and county offices to assist in emergencies. I have searched (a little) for such a design, and found something similar, made out of TV line, but would prefer something that could be made free standing and as small as practical. The Welding Rod antennas made with 45 degree radials are a little bulky to move through congested hallways. The idea is to make it portable enough to move from room to room as needed. Long radials would impede moving through hallways.
Thanks in advance, KE5GEO

4431. Re: 9 to 1 balun

>
> Gilles VE2ZTT
>

NOTE: With (Matching) Transformers "Baluns" it is the "Ratio" of the Squares
of the Number of Turns that 'defines' the "Ratio" of the Matching
Transformer.

Here are some straight math common examples:

* One to One "1:1" = (1X1) : (1X1) = 1 Turn to 1 Turn

A 3:1 balun would have a Turns Ratio of 1.7320508 Turns to 1 Turn

* Four to One "4:1" = (2X2) : (1X1) = 2 Turns to 1 Turn

* Nine to One "9:1" = (3X3) : (1X1) = 3 Turns to 1 Turn

Nine-to-One (9:1) Balun.
Primary (Antenna) Turns to Secondary (FeedLine) Turns.
21 Turns to 7 Turns

OR
30 Turns to 10 Turns

OR
42 Turns to 14 Turns

First: Use large enough wire for the Primary (Antenna) Windings to
cover 85%-99% of the ferrite rod's area. Or, "Space Evenly" the Primary
Windings 'far enough apart' to cover 85%-99% of the
ferrite rod's area.

Second: Wind the Secondary Windings over the Primary
Windings. Use the same size wire "Spaced Evenly" to wrap
the Secondary Windings to cover 85%-99% of the Toroid's
Area.

How To Make A High Power 4:1 Balun Info

There are mny plans available on the Internet for free standing
J-poles made out of 1/2 -3/4 inch copper tubing.

Good luck, jimbo

You might get some design ideas looking at the j-poles at
http://www.arrowantennas.com/

I personally have a j-pole made from a small length of 450-ohm line,
which could be made self-supporting with a wood dowel and stand.

Lotta ways to do this...

I know this has been discussed a bit in this NG. There is a surprisingly small amount of information in my antenna books regarding the spacing of HF antennas. I currently have a full wave 40 meter vertical loop and much to my pleasure it works great. It's built exactly the way one of the ARRL antenna books describes it.

I would also like to set up two 80 meter inverted V's in a HUGE pine tree about 100' from the loop. The two V's are for greater directional coverage and will have their own coax feed lines. I have a pretty good antenna tuner so I may have to run the inverted V multi-band if space is a problem. I also have a 10 meter rigid dipole that I would like to hang vertical. Finally, the "antenna farm" will include a fan dipole for 15 and 20 meters.

I haven't been able to find any firm rules regarding the spacing of the antennas. I assume a full wave length will be enough. Unfortunately, there may not be enough space for that.

Are there any "rules of thumb" I can follow for adequate antenna spacing? There will never be more than one antenna in use at a time with perhaps one exception of an additional receive only antenna for the shortwave. I'll be getting my General class next month and am chomping at the bit to get this stuff up! :-)

Thanks!

I'll bet there are even more newsgroup users who are tired of people
posting messages that have nothing to do with the topic of the
newsgroup.

I'll spell it out for you: The three newsgroups you have posted to
have nothing to do with a "moment of silence". There is newsgroup
which is a catch-all for amateur radio related items:
rec.radio.amateur.misc.

Now that you know, I trust you will post correctly in the future.

Bill, W6WRT

Please folks, do not reply to these posts which have nothing to do
with the purpose of this newsgroup.

If these clueless bozos never get any replies, they will eventually
learn to post to the correct newsgroup.

Thanks,

Bill, W6WRT

That may well be true but if you go over to uk.radio.amateur you might be forgiven for thinking that the sky is about to fall in. There a small number of individuals who are hostile and dismissive of newcomers but I recall similar behaviour 40 years ago.

This whole code thing has me snoring - I took my RAE in 1964, lost interest in the hobby but spent 25 years in electronics. At no time did I ever want to receive or send Morse code. Coming back to the hobby after 40 years I enjoy making gear and experimenting with antennas as well as winkling out dx.

I have to say that I will not be complaining because I can have a full license sans Morse code and it will not make or break me as an operator. What will make me a good operator is that I understand where and how I should be operating, that I understand my equipment and it's limitations and that I respect others users of the amateur bands. Plus, I am willing to listen and learn :)

Charlie.

Maybe you should stick to antennas Mr Smith what with you fancying
gay women and your nasty remarks about aids suffers. And let's not
forget your misogyny.

Your antennas don't appear to be at all sensitive and could do with
some tuning!

4452. How to measure RF Ground improvements - mobile

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-28 21:46:34 UTC
From: k1drw <k1drw@comcast.net>
Message-ID: <1167342394.028998.214750@48g2000cwx.googlegroups.com>
Source record: 47376

Can someone please provide guidance for this issue:

RE: a snippet from the SGC website:
"One of the great misunderstandings in checking grounds is
that just because you measure continuity with a VOM, that you will have
a good RF ground. You MAY have a good RF ground, but a DC measurement
doesn't prove it. Remember, if you measure the resistance across an
inductor, it will show zero DC resistance to ground even though it's
impedance at HF frequencies may be quite high. Continuity is a good
check, but it does not certify your RF ground system."

I would like to understand how/what to definitively measure before and
after I make improvements to my mobile HF system (additional
bonding/grounding). What metric will provide clear indication that I
have indeed made an improvement. I do have an MFJ-259 available. I
have been exclusively looking at the SWR for indication but I am
starting to learn that lowering the SWR is not necessarily an
improvement. Is it to simply to measure the mobile vertical feedpoint
impedance before and after ?

yes, all of them.

> Have you a book that says you cannot add curl to a Gaussian field ?

you may add whatever you want, but it doesn't make physical sense assuming
your 'Gaussian' field is actually the 'Electric'.

> I challenge
> you to find such a quote anywhere. You have never supplied anything
> that supports your views used to disparaged mine not one. Now David are
> you familiar with the NEC format antenna programs or familiar with
> matlab?

yes, i am the writter of a modeling program for lightning on high voltage
power lines that uses similar techniques to NEC and other large finite
element programs. And i am intimitately familiar with modeling systems in
matlab, simulink, and easy5. none of them will give you the answer you want
if you use them properly. use any of them improperly as you have been and
you can get any answer you want, even ones that aren't physically
realizable.

> I think that these are sufficiently disimmilar to show that if
> they arrive at the same conclusion it is not a fluke. Do you own any
> computor program of any sort?

i have AO and YO here, which are adequate for modeling amateur antennas. i
have used nec2, emtp, matlab, simulink, easy5, ansoft's 2d and 3d
eletrostatic and dynamic field analysis modules, written software for GE,
LM, GD, Chrysler, several US Navy projects, and EPRI. and am presently
gainfully employed working on a very large modeling project.

> Frankly I have the idea that you don't
> own one and have never played with one but then you may have one tucked
> away that you never use. What program were you capable of using, that
> you can now use even tho you are of advanced age?

pick one, but they are only as good as the input they are given.

> I am willing to give you the opportunity of doing just a little walk to
> prove your personal abilities. I can give you a dimensioned array that
> proves my concept and no matter what program you use you are welcome to

>
> YOU HAVE WON,
> I AM WILLING TO PROVIDE YOU AN ARRAY THAT DEMONSTRATES
> MY ASSERTIONS AND WHERE USING ANY MEANS THAT YOU WISH YOU CAN
> PUSH ME BACK TO THE STONE AGES AND STOP THIS NONSENSE

then build it and have it tested. that is better than any modeling that you
can do with existing programs, because none of them are going to prove your
concept... it just isn't physically realizable. i pointed that out on the
first example you gave and you never did seem to grasp the problem, go by
all means go back to the stone age, apply some heat to metal and build your
magic array.

>
> SHOW EVERYBODY WHAT YOU ARE REALLY MADE OF
> WHAT IS REALLY BEHIND THAT FACELESS MASK?

its only faceless to those who don't want to gaze upon it and understand.

Measure the feedpoint impedance with your MFJ. The resistance part of the measurement is the total of the radiation and loss resistance. A lower value of R means you've reduced the loss resistance by the amount of the decrease.

Hi Dave,

Now this will descend into parsing. To short cut that:
>>I can give you a dimensioned array
He's done that
>>that proves my concept and no matter what program you use
and has abandoned that (Art hasn't even proven it using whatever
program he uses).

What has been provided - 5 wires scattered in the air - have proven to
have been poorly documented vis-a-vis reportedly 50 Ohms non-reactive
when each and every wire has very little resistance and a huge
reactance. Also reporting gain (unsubstantiated) that in the face of
discarding 4 of those wires, that reported gain is trounced by the
gain of the one remaining wire (this must be extremely humiliating,
and why we rarely encounter any factual details from Art).

Which part?

The part where you top post, the part where you never snip the old
junk, or the part where you don't believe in paragraphs which makes
your stuff a royal pain in the ass to read?

<snip old stuff>

Please, Scott, Don't reply to Bill's endless replies to the people who have nothing to do with the purpose of this newsgroup. That way I don't have to see his posts. ;^)

Bill has undertaken a Quixotic effort to clean up the newsgroups. Every time one of these jokers posts something off topic, he sends off that message. He does the same in other groups.

Unfortunately, he didn't pay attention to the part in history class where they warn you to not become like your enemy, for he is now right up there with the worst of them.

But I do share your sentiment, Scott.

Seriously Bill, if you are reading this, I have to wonder what it is like to become the same thing as what you are fighting against....

I guess no one cares that Stefan come on here bitchin and moaning and
crying about the "dumbing down" of USA amateur radio, and he has no
apparent license.

How easily everyone gets fooled by these trolls.

> > SAN FRANCISCO: It may be the ultimate SOS.

You're right.

> > "We live in a society today that wants something for nothing."
>
> The written exams are "nothing?"

That's exactly right. That's why it was so important to keep the Morse
Code exam, because the written exams are nothing.

> > A female in a mostly male radio world, Kott is one of about 660,000 licensed

How can we miss it with the multi-postings? But in order for *you*
to see the charade, I'm afraid a mirror will be needed.
You piss and whine because no one can understand the silly
jibber jabber you throw out...
You piss and whine because no one will try to do or repeat work *you*
should be doing, or already have done.
The solution to your problem is actually very simple, and Dave has
already
given it to you. Build the dang thing and see if it works as you say
on an antenna range.
If it works as you say, *maybe* someone will see a use in it.
If they do, *maybe* you can sell it. Simple. You don't even have to be
born in England to fiqure that one out. A dumbass redneck Texan
like I can see that simple solution in a half second.
If you build it, and it works, maybe they will come.
If you build it and it doesn't work, probably they won't.
To foist among the public a "miracle whip" which you haven't even
taken time to test in the real world is the ultimate charade.
I can make a puter modeling program spit out nearly anything I want
if I caress it in a favorable manner. I imagine others can too. Ask
Cecil about his dipoles that show in excess of 20 dbi.. Sure the
"supergain" can be there *if* you can get power to the antenna with
that super low feedpoint Z. Good luck in the contest trying to achieve
this
task. I bet I could keep up with you using a regular coax fed dipole
and
5 watts power.
You seem to require our permission for you to tinker with this new
miracle whip array. Well, you have my official permission to knock
yourself out.
BTW, why is it that you can't make post without whining about Roy,
Richard, Dave, etc, etc.
I was building a new fangled miracle whip, and they told me it wouldn't

work as planned, I'd tend to listen to them myself. If I had trouble
believing
them, I would build a real antenna instead of arguing about it on
usenet.
If your theory? is correct, it should work as planned. If not.. Well...
Time to conjur up a new miracle whip.

Lurk mode off, and back to those silly boat wrecking rednecks in
Deliverence..

You have to hand it to him! He did a good job declaring his views
ragarding ham radio
ande he may be right. Ham radio is shurely on the downslide and we
can't blaim that on the FCC. We have the internet now that welcomes
everybody so it wouldn't hurt us if the FCC gave somebody else the
frequencies. We talk of public service well looking at this newsgroups
work it would be better for the whole world if America got off the
bands because we are not liked anymore and this newsgroup does not do
service to America other than showing who we really are.

Woe is Art. Yes, it is true. We have bludgened poor ole Art into
obvious
submission. Beaten down, bloody, but not whipped yet!!!, sayeth Art.
Isn't flogging the practice of using those tassled whips against ones
own
body, or am I thinking of something else. I may be confused, cuz I R A
redneck. If I'm thinking of the correct term and practice, then this
would fit well.
Why? Cuz every time I read one of your posts, I get the impression you
are
flogging yourself with one of those tassled leather whips.
To an innocent bystander, this might give the impression that Art is
battling a mighty heavy fly problem. Or maybe he itches badly.. I
dunno..

Woe is Art.
Woe is Art's latest antenna too.. There I said it. A big slap with the
tassled
miracle whip I give to thee.. :/
Woe is Art.

I believe you know nothing about China and you most likely have never visited there. If you had, you would know that China operates as a market economy within a socialist state, not a slave state. You would know that the standard of living in China is quickly rising above most other countries in the region, particularly the democracies (and certainly South Africa) and it is a very exciting place to live right now. But you are obviously innured by whatever media is brainwashing you at the moment and your statements bespeak your total lack of intellectual credibility. If one is from a country other than the US and undertakes via public statements to criticize or patronize the US in a forum, fine, but then the person should be man enough to take a bit of reverse criticism without having to depend on nannys such as yourself to defend them.

Nope.. I'm on a new movie now... The boat wrecking rednecks went home.

> I am anxious to swell the
> rankings of this group, it seems to get bigger my the minuit

Not me.. The more posts, the longer it takes me to read them.
People, lets keep things simple if you please.. Thank you.

>Advertise
> the newsgroup of Ham Radio so we can get the numbers up of people like
> yorself a perfect example of what people are missing by not joining us.

This place is a hoot, thats fer sure.. CW, CB, Rednecks, Miracle Whips,
heck, what for can you ask for?

> We are so much better than CB if you like the fighting banter

This ain't ham radio or CB. This is usenet.

> Cheers and beers

Well, I might have one new years maybe... But I generally don't drink
anymore.
And if I did, it probably won't be a beer. More like a big Texas sized
heaping
helping of Crown Royal, the favored brew of us fisticated rednecks.
But I probably won't, cuz it would give me brain damage the next day.
I can't afford to lose any brain cells if I want to deal with sharp
guys like you
on a regular basis. :/
Woe is me..

4474. Remembering some past antennas (CB related)

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-29 04:06:02 UTC
From: Gary KW4Z <kw4z@charter.net>
Message-ID: <C1B9FE5A.16587%kw4z@charter.net>
Source record: 47398

Before I became a Ham (Amateur Radio Operator) I got my introduction to 2-way communications via CB-Radio. Hey can't argue too much about it that's how I met my wife some 31 years ago. Anyway I remember (during the Boom times) how many manufacturers produced some pretty good antennas that seemed to have great gain and results. I always wondered why they never applied some of their methods to Amateur Radio Antennas (well not Shakespeare because of their high lightning susceptibility).

I wonder how many of the old standard base station antennas are still around in use or for sale? Such great antennas as the Avanti PDL Quad or Avanti's Astro Plane or MoonRaker series, or Shakespeare's "Big Stick" which was so prone to catching Lightning, or the original "Starduster"? I know that now, these days the Starduster and the Astro Plane are built by the same European business that purchased the rights to build each but for this post I'm not talking about the newer Astro Planes or Stardusters but rather the original models. The Big Stick I think has just faded away but I know there are still some out there.

Maybe it was just youth but I thought those were great antennas and the only Amateur antenna that I really sang praises about was a HyGain HyQuad which actually stood up to an ice storm pretty well for me. Sold long ago but wish I still had that thing. I think the only ones that liked it better than me was the birds.

Most, if not all, cb antennas came from others work in the past. The 1/4~ ground plane was in use in amateur communications long before cb, so the yagi beam, the quad beam, etc., etc.

Indeed, I don't know how long it has been now since I have seen anything "really new" in antenna theory, design, or construction ... a decade? Two? Three? Four? More?

I think you will find most hams had the ability to build their own antennas (knowledge, source of materials, help, etc.) and found that a much more economical way to go. Plus, there is much satisfaction in building ones own antenna. And, it is easy to produce much more robust and quality when doing so, as opposed to manufacturers who have to pay attention to cost at every level.

Regards,
JS

No he is being realistic. We have more CB sets out there than ham sets
and they are no different to hams. If there is an emergency then CB ers
would probably do a better job than hams and with less quibling. I
think the writing is on the wall for ham radio since they dont provide
a thing for the country It would be better if home security took over
the frequency as we all now use the net instead. Have you heard anybody
on the radio lately if you get my drify

Ham radio has really lost out on its usefullness to the Country. There
are more CB radios in the country than radio sets and truck drivers are
sure a better resource than ham radio running around with walky
talkies.. We used to be on the cusp of radio but now we are in a throw
away economy and very few hams know how to use a soldering iron.
Wouldnt the frequencies be of better use to Home Security rather than
advertising to the World what americans will do to those who are
against us?
Listen to the radio now, nobody is using it and we are crying to the
FCC but for what ?
Ham radio died when the net was formed and hams moved to newsgroups
where they can argue better than they did on their own special
frequencies.. We sure as heck don't need a newsgroup for antennas until
the old guys die off and even then we have books with everything has
now been written down. Seems like we are going back to the old days
where the old timers couldn't accept
cbers as being upto par with respect to radio knoweledge. In ten years
all the old fogies will die off
and the World will move on without a mistep. Hams have over estimated
their abilitiues and worth
to the Country and it is time we let go

How can ham radio justify holding on to valuable frequencies when
comunities
can put them to good use?

Listen to the bands now, nobody is using them yet we are denying
services required by people outside of the metropolis. We have the
internet now and hams have moved to it, as with this newsgroup. There
is no good reason for us to deny the FCC putting it to better use for
the Country

Agree. I have made copper pipe j-poles for 50,144, 220 & 440 bands. They
match well; sometimes I can hit 1:1 at the sweet spot. They are virtually
indestructable and very cheap. Gonna do one for 10M next. (It'll be about
24 feet tall and will likely need guy ropes.)

Horrors! Isn't Ham Radio ALL about "working DX on HF with CW?"

Why...why...why one HAS to "get on the air" and "work" someone
by morsemanship! "Rite of passage" or some other BS myth...

One just "cannot" be a "ham" without "working someone with CW!"

:-)

Source record: 47408

Granted, and totally right. After achieving my Amateur Radio license and purchasing a Kenwood TS520S I built my first antenna, an inverted Vee. Worked great but my point, about the post, was that many of those CB antennas, for using 4 watts only, really did shine and the noise rejection or level of noise with some was tremendous. I wouldn't take anything away from Ham's building their own antennas and feel that's the best way but I do miss the jumps in design account of the CB Boom of the 70's.

Source record: 47409

I have to take exception with you on a few things, however I can see why you would think the way you are, and it's a lot of our own doing and fault. I still think Amateur Radio is very useful to the public and local Governments. Today, many clubs, ARES, and RACES stations still assist State Weather agencies with trained Weather spotters that during an alert respond and set up weather nets on the VHF & UHF frequencies as well as driving around to be a trained eye on what's going on. Amateur Radio operators also, though much has broken down or been forgotten, are trained and many participate in training at running an organized net. Several nets meet on each frequency with State Level nets still assigned to 75 Meters although as dormant as I have been I don't know that active status of them but I assume them to be going as they are still a part of the National Traffic System. Mostly useless, to most, they still give a Ham a structured net to observe and that could be activated during disasters like Katrina where Hams can transport repeaters into the area or work simplex from riding with police or national guard. Health and Welfare traffic from hospital to hospital can also take a load off FEMA or other agencies and attempt to locate relatives that are at each hospital provided they get help from each hospital. During Hurricane Season 20 meters is turned up for Tracking and Health and Welfare messages.

Like you said though much has died off and people don't seem to care much more but the underlying network is there and Unlike CB we are trained (you had to study theory, rules, and operating procedures) operators that at least know how things should run. I think it could improve but with the internet, newsgroups, online chat as well as Cell Phones everywhere Ham Radio has sure taken a substantial Hit. I do think though it can and will regain much of what you accurately see that it's lost.

I don't know how many of our new 6 hour hams I have worked on 40m who are using a Station Master (a 11m half wave with a base parallel tuned matching network) fed with 20m or so of RG58C/U and an ATU on 40m, and astonishlingly, VSWR is less than 1.01!

We owe a lot to that CB technology!

Owen

4487. Delta Loop Ideas Please

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-29 10:35:40 UTC
From: John <Q.R.Z.@dxdx.co.uk>
Message-ID: <4594ef77$0$31222$da0feed9@news.zen.co.uk>
Source record: 47411

I have been researching for a while now around the area of nested delta loops. I want to upgrade my multi-band vertical antenna with delta loops, each one resonant to cover 20 to 10m. However there is nothing on the internet about nested delta loops. My wish is to have the delta loops orientated such that they are pointed at the top and fed one third of the way up one of the vertical sides to get a low angle of radiation.

I realise that they have an impedance of around 100 Ohms and this would need to be matched. The usual method of doing this is to use a quarter wave length of 75R coax to match to 50R.

Much in the same way that parallel dipoles can be fed with a common feeder, can 5 delta loops be fed via coax matching stubs with a common 50R feeder? (i.e. bring the ends of the matching stubs together?).

I tried in the summer to nest 5 delta loops with the feed point as described above and then brought the feed points together (without matching stubs) , however it is not physically possible to do this - they really need separating out.

Any ideas any one? My basic aim is to have 5 resonant antennas with no tuning unit involved.

Thanks

John

> Glad there are some lurkers out there to see this charade

the only charade is your rather transparent attempt to draw those on here into a fight. you'll need some better technical material to do that though. your other postings about the death of ham radio and its replacement by the internet make this even more obvious, you never wanted to discuss antennas, you just wanted to draw someone into an endless discussion of your bafflegab. the problem is, you didn't have anything good to start with, i have successfully done that on this news group, but you have to start with the right lures and enough knowledge to keep it interesting. you degenerated too quickly to name calling and lost all technical interest, so good bye and enjoy the new year alone in your thread.

Source record: 47414

Roy knows whereof he speaks... Just for fun let me stir the pot here and introduce a different way of looking at the mobile antenna system...

The mobile antenna can be viewed as an off center fed dipole (OCF)... The mast and top hat form one side of the dipole and the vehicle (the so called ground) the other side... The problems I see - besides the low radiation resistance of the electrically short mast and "ground" - is that the L/D ratio of the two parts of the antenna are vastly different...
The mast portion has an LD ratio of ~20 < picked out of thin air, I am sure someone will correct me>
The "ground" has a ratio of less than 1.0
This massive offset in L/D between the two parts of the antenna system results in massive skewing of the capacitative coupling to actual ground on each half of the antenna...

What I propose is to not connect the RF of the antenna system directly to the vehicle chassis... Use an insulated mast as usual, but do not connect the coax braid to the vehicle... Instead, use the braid of RG8 as a radial/counterpoise to the mast... Run the coax underneath the vehicle and wind it around the perimeter leaving it a shorter than an electrical quarter wave... Leave it insulated from the vehicle... Seal the ends against water and salt intrusion... Use a coil at the feed point to establish resonance on this counterpoise... Compare the field strength to the conventional method...

Can it be done, - yes...
Will it work well - maybe!
You are going to have mutual coupling between the loops messing up
resonance and impedence... You cannot just cut the loops per the
formula and nest them inside of each other, connected at the feed
point, and still be resonant... That is your first problem... Search
the literature on triband quad loop beams and their results will point
the way to the appropriate modification of the usual loop formula...
Next, your impedences will drop and 100 ohms is not likely to be the
number...
For a single feedline try a quarter wave of twin lead from the mutual
feed point to each respective loop... Personally, I would use relays
to cut out the unused loops and save myself a lot of cut and try...
ymmv...
15 -17 will talk to each other... Try hanging them at right angles...

If there's anything other than politics and Morse code to argue about, especially in RRAP, it must be all the disgusting garbage offered by the resident lunatics and the 45-year long rant that would even turn the stomachs of the gay people they malign.

Certainly you have a thread about the best new gear that became available this year or the best influence on the hobby.

At least I cannot get these "posters" if I read a printed radio magazine.

4493. Re: Distance between antennas

Any antenna will couple to some extent to another, especially if on the same band... I have modeled my 80 meter antennas with spacings in excess of 1000 feet and they still distort each others pattern... I use relays to detune the unused antennas...
Now, your inverted vees at right angles on the same support will work OK... I don't know that there will be a big difference in patterns, I suspect less than a half S-unit at best... But try it and let the group know your results...
There will be less couplilng between antennas on different bands and while there will be some pattern distortion what you lose in one direction you will get back in another... I would hang the antennas and go for it... Drop us a line when you are ready to go and we can make a sked to work you on 80...

> 73, dennis, k1drw
>

Dennis, assuming you've already done at least some "bonding and
grounding," further measures may have a fairly small incremental effect
on loss resistance and efficiency. The MFJ-259 has a resolution of one
ohm and the uncertainty of that LSD is probably more than an ohm. You
may not be able to reliably detect small improvements using the MFJ.

These issues may be less troublesome if you use field strength
measurements to detect changes.

Plan carefully, because once you make a change in the system, it is a
pain to have to un-do it in order to apply a different measurement
technique. Will you share your results?

73,

Chuck

I hear ya man! I have decided to reform and quit replying to his canned messages. I feel it's just like talking to a brick wall, so it is a waste of my time. I guess I just have a bit of an aversion to people dictating what I (and evryone else) do based on the dictator's beliefs. I've always been of the belief that with newsgroups, I read the subject line and if it doesn't sound like something I can help with, I don't even read it and move on to the next message.

Now, on to antenna topics...does anybody know if Alford slot antennas for say 902 and up would be decent mobile antennas to get a decent horizontal omni radiation pattern?

Whoa! Just because YOU don't use the radio doesn't mean the rest of us don't! What's the need to give these frequencies up for home security? Ham licenses are a privilege, not a right...they CAN be taken away and then they would be gone forever. Home security can better be effected with a gun and owning a gun IS a right, which they can't take away (although they ARE trying). I prefer Ruger, Remington and Smith & Wesson home security systems.

Scott
N0EDV

PS...According to qrz.com, you're ham license is about to expire (and you appear to be one of those "old guys" you mention. Are you about to expire as well?

Yup Gary Ham radio is all..... could have..... should have... but
really did nothing

The old spirit carries on at morning coffee breaks. I remember when the
club was over 100 strong and where people resented incomming CB ers who
in actual fact kept ham radio alive even tho the old timers talked
about wire antennas and making power supplies or a tuner where as the
new comers just bought their stuff and accepted that all was known
about antennas. Went to a ham fest last year and there was lots of
people there at the beginning of the first day but by lunch time it was
empty and some vendors were packing up. The old timers already had
their equipment and there are no newcommers to buy unles it is computor
related. Ham radio still thrives in other countries where the thro away
economy has not taken a full hold but their repeaters show evidence of
being taken over.
This newsgroup is an excellent example of us old timers taking the
hobby with us to our graves. It is ours, we made it what it is and this
newsnet is its last gasp where pseudo experts try to keep their spirits
up as father time works on schedule

Yup, if it wasn't for CB the retail market wouldnt have done so well in
the past. Today we have no newcomers to buy things prefering to zero in
on computors which is what the ham community is also doing tho to a
lesser extent since age prevents change somewhat.
Coffee breaks are now in vogue except for the few who miss the
perceived statue they once attained and where others can pile in with
grammer punctuated by swear words. But that is the same all over
America we are a split society and continue to grow that way knowing a
few bad apples will always overcome the britest in the barrel.

Hey, what about our present "public servants"?? Look at what they're
made up of and they "shine" as exemplary role models. Not exactly!
Maybe we should get rid of them since they set an example as good as
most hams (according to you) ;)

>above and then brought the feed points together (without matching stubs) ,

Hi John,

Without matching (stubs? these are usually shorted or open - perhaps
you mean lines) seems to go against your goal of a 5 band, no-tune
antenna. The alternative is to have 5 matching lines, a lot of wire
in the air.

>however it is not physically possible to do this - they really need
>separating out.

It would seem to be physically possible, just not elegant, nor
successful.

If you are willing to invest in such complexity and wire, why not ONE
antenna that does it all without such grief? Consult:
http://home.comcast.net/~kb7qhc/antennas/verticals/Cage/cage.htm
or
http://www.qsl.net/kb7qhc/antenna/Discone/discone.htm

Hi Chuck,

This is rather focused at the wrong end of the scale. The antenna's radiation resistance is going to be lost at the 1 Ohm resolution of the scale. A 12 foot radiator in the 80M band presents us with about 5 Ohms (a 10:1 mismatch) resistance with so much reactance that it would wrap the needle around the peg at the wrong end of the SWR scale.

However, the "lucky" ones may in fact see a SWR that is closer to 2:1, only to be satisfied that 20 of those Ohms comes from poor connections, coax, heated coils, and chassis loss. We can all agree that the MFJ is perfectly capable of measuring 20 Ohms without issues of error (yes, there will be error, but it won't be focused in the last digit). You will also be able to see that 20 Ohms diminish TOWARDS the 5 Ohm Rr when you struggle to IMPROVE the situation. Even if that is everyone's goal, it is rarely achieved; and certainly not because accuracy foiled them.

Hi Scott?

What is that you want decent mobile operation, or decent horizontal
pattern? At 902MHz is there much call for horizontal? Especially in
a mobile?

Consider the Inverted F at:

Hi Richard,

It would surprise me to see a 15 ohm reduction due to incremental
grounding and bonding. I would expect changes in R to be in the range of
a few ohms: right up against the uncertainty of the instrument.

But if he can bond a fender to the hood and see a 15 ohm reduction in
loss resistance, I admit to raising a non-issue. ;-) You and I are
simply expecting different performance results from the incremental
grounding and bonding.

Absolute accuracy is unimportant in this application.

73,
Chuck

>Absolute accuracy is unimportant in this application.

Hi Chuck,

Quite so, hence the last digit is merely resolution, and the resolution of 20 Ohms of loss against an Rr of 5 Ohms is easily resolvable, and its reduction is easily seen. Further, automatically assigning an error of 1 to the last digit presumes the underlying measurement hasn't been rounded up from a smaller range of error. Given the product is MFJ, it is hard to credit it with that kind of craftsmanship. However, even with a 1 digit error (which has been presumed to be quantization error), it will always be inherent in any Relative reading. If 20 Ohms reading is actually 19 to 21 Ohms of loss (irrespective of absolute accuracy), then driving out 1 Ohm of loss will actually be 18 to 20 Ohms exhibited as 19 Ohms. The only problem here is that you may have to drive out slightly more than 1 Ohm to kick the reading down to 19.

If you cannot drive out more than 1 Ohm of loss out of 20, then there's no point in trying, is there?

Dennis,

If you've followed the discussion thus far, you can well expect that the SWR will climb as you drive out loss. This means you need to anticipate matching to something like a 5 Ohm load (in all likelihood, as described here, it will be higher). Drive out the reactance and use a 9:1 UnUn. Beware that such an UnUn will require 16 Ohm transmission line (if it was all that easy, everyone would have stopped posting similar problems like this long ago).

> (i.e. bring the ends of the matching stubs together?).

Not necessarily no, but I think it will give you a headache. If you
don't have antenna modeling software on your side, you're going to have
to do it experimentally and you're probably not going to get much help
on the internet. You might consider going with full-wave rectangles
that are twice as high as they are wide. They don't need any matching
stubs; they're 50 ohms to start with.

There will be big interaction among any 5-HF-band loops at any rate.

You might do better with switching all five feedlines with a remote
coax switch of some description.

Heh Bill How about you making a list of people that you talk to that we can't?
With your advance age it would be better if you wrote things down before you expire.
We are all enjoying this treat of showing to thw world what ham radio is like in America,
You have to be for us or against us as for the latter bring them on America can do anything
it chooses to do wel let us say that a bit different America will do what ever our president tells us to do. Now thats much better Are you enjoying all that money we took out of the economy Bill before we sent the work overseas. I got to see a lot of different places while doing that but we have still a long way to go before we can get the wages down in this worls economy. Amnericans just have to learn to eat just twice a day and work harder if they are going to compete. If they don't we will bring into the Country who are willing to do those jobs that Americans wont do. And dont send your kids to college where they get loaded up in debt, the big companies here are bringing in so many Indians the next cricket test match is going to be played in the mid West. There will be a small section left for the poor to stand and watch. State Farm is making a fortune here and the economy they say couldn't be better. They gained several billions this year by not paying out on disasters or replacing auto bodies made cheaply overseas. It is a non profit corporation which means all excess goes to the big superviser who hit on the idea of bringing in ofshore help.
Only in America where the belligerent and the greedy always win
Art

> for you

Nobody has to invent them, they only have to repeat the ones you've
posted. There are morre than enough to go around.

A rather odd statement.

How does one measure "code usage"?

It went "up" compared to what?

It went "up" according to one observer who somehow could simultaneously monitor all bands everywhere in the UK? Do you also count the code usage of DX stations communicating with all UK hams or do you only count the UK side of the QSO's? What was the actual amount of code usage prior to and then after the elimination of the requirement? How do you express a unit of code usage? (dits + dahs)/sec/Hz * unit time?

I have lived in the U.S. most of my life ofcourse I would grow to be part of American life. You are either with us or against us. If you don'/t love us then we will set Israel upon you The All Gaze prison is still locked in but we can get you a free pass. Bethlehem well that is cut off to by the Israelis as they have no interest in the INN coming it to use again The constitution says we have the right to pursue happines and as the president says that doesn't give you the right to obtain it and he is pretty true to his word. Im glad ham radio has deserted the airways to get on the net so that we meet every day people in the World and tell them how things are going to be ,or else!

Hey Len, you've been flaming code on these groups since at least 1996...I can still remember when you got on the rec.radio groups the first time. Somehow, as a brilliant electronics engineer you were never able to master the skill of sending and receiving letters represented as dits and dahs and this kept you off HF...but you always had vastly superior academic skills in the field of RF that fact seemed to make the skill of simple Morse communication seem so irrelevant in today's modern world.

Now you no longer need that skill and the doors have swung open. Does that mean you will make yourself and your brilliant mind available to the unwashed masses of hams who only know how to pound keys? Will you now be getting your extra class and dazzling us with new ideas and inventions that will forever modernize the amateur modes, you know, the sort of achievements you always said would be possible if only they got rid of that nasty Morse test?

We will all be waiting Len.

Can I have both? ;) Well, around here (the Chippewa Valley area) in WI we all use horizontal on all bands from 6M and up. Actually, I was just thinking about an Alford slot in the mobile since it is supposedly fairly omnidirectional and horizontally polarized. Seemed it might be OK for driving around and listening for my beacon or maybe an operator or two if they also were using an omni horizontal antenna. There are several of us on 902 within about 15 miles of each other...

I'll check out the inverted F on the website you cite. I'm guessing it will be similar to the innards of blade antennas made for the VHF/UHF aviation bands...

Yup, you have to have a gun for when the balloon goes up but shouldn't
you get an automatic?
If you live in a city it may be a mob coming for you instead of just
one person. It is not like hunting you know when you shoot at an animal
running away, when it happens it is a finality
you either get them or your wife gets the life insurance, in a way you
can't lose.and the other guy has to deal with what is left. Had a guy
come over one time and wanted to know why there was a light on my
tower, after I told him it was set up with a 28 day recorder which
wasn't in the house we never saw him again. It is imperitive that you
leave a record of the goings on around your home it only costs peanuts
and the number of deaths by violence is going up. You can't be to
carefull in America these days and besides we may have a revolution and
anybody with money gets Madame Guillotine. Isnt that the American way
when mayhem breaks out the first looter gets first choice

Perhaps in some ways. Keep in mind that in having passed it, you now know that you are able to learn this. Therefore should you wish to go further with this aspect of amateur radio in the future, you will have the confidence to tackle it and get it into usable shape. This gives you a great advantage over those that listened to the bull about it being "too hard" and thus were afraid to try and will probably continue to be afraid to try.

No you can't. There was no Stefan Wolfe here in 1996. And there is no
amateur radio license issued to Stefan Wolfe.

> Somehow, as a brilliant electronics engineer you were never able to master
> the skill of sending and receiving letters represented as dits and dahs and
> this kept you off HF...

Is that what's been keeping you off of HF? No license is issued to
Stefan Wolfe.

Odd, but Len has been on HF through SHF. All without code.

> but you always had vastly superior academic skills
> in the field of RF that fact seemed to make the skill of simple Morse
> communication seem so irrelevant in today's modern world.

Len's knowledge of RF had nothing to do with it (sorry Len). Morse
Code became irrelevant all by itself.

> Now you no longer need that skill and the doors have swung open. Does that
> mean you will make yourself and your brilliant mind available to the
> unwashed masses of hams

There are no unwashed masses of hams. Maybe there are a few
individuals at hamfests that might pay more attention to personal
hygeine, but no masses.

> who only know how to pound keys?

Welp, there are a bunch who know how to pound their chests. That's
what the ARRL VP was saying when K4YZ attacked me.

> Will you now be
> getting your extra class and dazzling us with new ideas and inventions that

How about if he does as much innovating as has N2EY, W3RV, K0HB, K8MN,
and K4YZ.

Hmmm? Did I leave Cecil off the list on purpose?

> We will all be waiting Len.

We? You are trolls?

Joe, it doesn't. There are lots of 20WPM Code-Tape Extras - who've
never had a single CW contact in their lives and never will. If a ham
must be judged, judge him or her on their conduct and value that they
add to the service.

Of course, your question is rhetorical and nobody knows if you are a good amateur, or a bad one, or what it might take to make you a better one.. Your might be a 75m late night quarmer or you might have provided significant radio communications for rescuers during the San Farncisco earthquake. Who knows?

Passing the code test used to simply increase one's qualifications; it obviously did not in itself make one a better practitioner of the service. Now ,of course, passing code has no meaning at all; it is similar to Cecil Moore having passed the mensa test.

Did passing mensa make Cecil a better engineer?

Only the Logo. With the corporations purchasing other corporations
in the electronics industry (as a whole), it has been difficult
keeping up with the new names in three decades. [it's been worse
in the microwave portion of the industry...]

However, hams who get their ONLY 'radio news' from ARRL wouldn't
know about such things. <shrug>

Absolutely. In US ham radio all must be white male HETEROsexuals
who love honor and obey morse code.

>> Hmmm...that alone makes one wonder about Ms. Kott's motivation?

Google never forgets. Last night I did a quick copy of the
All-Time Posters on RRAP and here is what they had for 28
Dec 06:

K4YZ 11,945 [warrior of Seven Hostile Actions]
Cecil Moore 11,892
James Miccolis 8,836
Dick Carroll 7,091 [SK]
-me- 6,191
Eric June 5,434
David Heil 5,358
Ed Hare 5,253
Mark Morgan 4,633
James Rosenthal 4,286

Grand total of just the Top Ten: 73,919 posts!

Cecil has been in the newsgroup perhaps the longest, finally got
tired of it and went over to rec.radio.amateur.antenna. June,
Hare, and Rosenthal haven't been here for at least two years.
Major Dud finally grabbed more archive space than Cecil (which
was expected) even though he mainly talks about HIMSELF and his
mighty "military" service while personally insulting everyone
who dares disagree with him. :-)

73,
LenAnderson@ieee.org

I wouldn't say it makes you a better ham for having passed the code test.

I would say it makes you a better ham because you are now familiar with
another operating mode commonly in use in the amateur radio service.

Likewise, I would make the same statement -- it makes you a better ham --
regardless of the mode of operation -- CW, SSB, FM, AM -- you name it.

Why? As an amateur, experience with ANY mode of operation, IMO, makes you a
"better" ham.

Yes, but I discovered the ACME units in a dusty warehouse (is there another kind in AZ?) out at the DMAFB "boneyard" http://www.dm.af.mil/units/amarc.asp and bought them surplus for a song.

I'm putting them up on eBay at midnight on Dec 31. In exchange for keeping them safe, I gave one to my biker friend, "Tiny". He and some of his friends are out in the garage installing it on his Harley. He missed the Harley-Davidson 100th anniversary in Milwaukee in 2003 but he's planning to go back when the ACME drive is installed and tweaked.

In addition to the fact that the auction proceeds should allow me to take my jet down to my new retirement home on my own island in FO land, I'll be glad to see them go for another reason Since I brought them home the damn coyotes around here have been howling like paparazzi at a Brittney Spears Girls' Night Out party.

Wes N7WS

ps. Brittany used to own a pinch of unobtainium but I believe she peddled that on eBay too.

4540. Re: Why doesn't the FCC put the bands to a better use ?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-30 02:32:39 UTC
From: Gary KW4Z <kw4z@charter.net>
Message-ID: <C1BB39F7.169DB%kw4z@charter.net>
Source record: 47464

I too remember the criticism and skepticism thrown toward CB Radio, much maligned in many cases true in some, regarding the professionalism that they perceived was lacking. Whoa be to Ham Radio as the CB'ers upgrade and get a taste for something better. You are correct, or those that say, that CB'ers or many of them helped Ham Radio along as they would attempt to upgrade and improve their lot. Many Hams, some former CB'ers" granted exercise much less restraint and professionalism on Voice (75 meter bands) at times so we are just as guilty as the others we throw rocks at. I still do feel there is hope but like everything else it takes time, dedication, and being an example as well as having the desire to see it improve. Those "coffee break" gatherings were unique and in spirit at times the club meetings or Morning Get to gathers resemble a much smaller variant of the same. Truckers will always define CB as it's their business radio, and many find company with the other long haul drivers. Thankfully many a truck driver is also finding Ham Radio and many keep a rig in their trucks as well and provide yet another source of good operators. Sure there are some bad ones but that's the way it is everywhere (even in Churches). With the dropping of the Code requirement you never know how many, existing CB'ers' will upgrade and help us hold the frequencies that we have now. They ARE a priviledge and without a base to use them and using them it's increasingly easy for the FCC to look for commercialization of our bands. Thankfully most Commercialization is being done way above where most of us use but you can't write off anything, not to mention what others in the World Do.

> -me- 6,191

No, Len, that number is way too low.

According to Google, your postings to rrap since 1997 are no less than:

846 as len.anderson@mogur.com
1230 as nocwtest@aol.com
10 as averyfine@aol.com
39 as averyfineman@aol.com
1204 as lenof21@aol.com
6210 as lenover21@aol.com
1454 as lenanderson@ieee.org

That's a grand total of no less than 10,993 postings to rrap, under no less than seven different screen names, all by you. There may be more - 10,993 is a minimum number.

Google never forgets.

If your ability to count *your own postings* results in a number that is so inaccurate, why should anyone trust your counts of other things?

If your ability to represent your own history of posting to rrap is so error-filled, why should anyone trust your recounting of other history?

Any instructions on just how to do that? I'm relatively new to this hobby.

Maybe he was a UK ham troll then?

Was I on that early? :-) I was on BBSs and doing letter-
writing a lot earlier than that, over a decade before.

>> Somehow, as a brilliant electronics engineer you were never able to master
>> the skill of sending and receiving letters represented as dits and dahs and
>> this kept you off HF...
>

>Stefan Wolfe.
>
>Odd, but Len has been on HF through SHF. All without code.

From VLF on up through 25 GHz...transmitting LEGALLY. :-)

I've never described myself or even implied that I was a
"brilliant electronics engineer." I've had lots of industry
experience in radio-electronics since 1952 (military), then
beginning 1956 (aerospace) in southern California. ONE radio-
relevant US patent, 3848191, issued 1974.

I had managed about 8 WPM in receiving morse code in the 60s,
then thought about the uselessness of such effort seeing as I
had worked in Big Time HF communications a decade earlier, all
WITHOUT having to learn or to use any morse code. The minimal
was then 13 WPM for a ham license. I'd already had 3 years of
military experience, leading to operating team supervisor, on
long-haul HF circuits across the Pacific and south to the
Phillippines, using RTTY and SSB (multi-channel commercial
kind) with some old-standard FAX plus being supervisor grade
on multi-channel microwave radio relay equipment. So *WHY*

was this old, old morse code so damn important to amateurs?
Came to the conclusion they all wanted to just recreate a
pioneering past where very few had participated, didn't really
go in for the comradeship that was supposed to be in ham radio.

Besides, CB had been created in 1958 and that was good for
local communications. The Los Angeles area didn't lack for
'other communicators' in the early 1960s. :-)

>> but you always had vastly superior academic skills
>> in the field of RF that fact seemed to make the skill of simple Morse
>> communication seem so irrelevant in today's modern world.
>
>Len's knowledge of RF had nothing to do with it (sorry Len). Morse
>Code became irrelevant all by itself.

Where the fork do these TROLLS come from, Brian? :-(

This twit obviously wants to FIGHT with words. Poor guy is
already gunned down and carted off to Boot Hill but he not
know it...

On the other hand, I've memorized a few formulas a tad more
complicated than Ohms's Law of Resistance...so that probably
is "rocket science" to some amateurs.

>> Now you no longer need that skill and the doors have swung open. Does that
>> mean you will make yourself and your brilliant mind available to the
>> unwashed masses of hams
>
>There are no unwashed masses of hams. Maybe there are a few
>individuals at hamfests that might pay more attention to personal
>hygeine, but no masses.

Hmmm...the average ham mass is about 77 Kg. :-)

Maybe the desk-bound contester is 10 Kilo more from sitting
in front of his raddio for so long? :-)

Just WHAT am I supposed to "make available" to those ham
"masses?" Does Steppin Wolfe expect miracles from the
brass-pounders who've tried to pound ME for years about
their love for morse code?

What happened to all the "smarts" among the brass-pounders?
Why couldn't THEY do the "innovation" for their "unwashed"
brethren? None of the brass-pounders seem to answer that.

>>> who only know how to pound keys?
>>
>>Welp, there are a bunch who know how to pound their chests. That's
>>what the ARRL VP was saying when K4YZ attacked me.

Some of those Mighty Macho Morsemen pound what they think
are the chest mass of King Kong...but are still little
code monkeys dancing to the manual morse organ of that
publishing house in Connecticutt. I doubt many of them
could climb even a few stairwells of the Empire State
building in NYC...with or without biplanes buzzing
around trying to shoot them.

>> Will you now be
>> getting your extra class and dazzling us with new ideas and inventions that
>> will forever modernize the amateur modes, you know, the sort of achievements
>> you always said would be possible if only they got rid of that nasty Morse
>> test?

Tsk, the Troll from the UK has strapped on his holsters
and wants to walk down the street for a shoot-out... :-)

Thinking back to what I've written in here, I've NOT said
much about "achievements possible if the code test was
removed." That wasn't my point. The code test for an
AMATEUR radio license was just an anachronism, a left-over,
something that mattered ONLY to the very old timers who
had to take it (and therefore everyone else has to take it
too).

Amateur radio IS a fine, absorbing HOBBY pursuit. It should
be open to ALL who can qualify for the license through the
written tests. It is *NOT* nor should it ever have been
some kind of Living Museum of Archaic Radio Technology. But,
in the minds of the pro-coders, that's all it was...a
Living Museum of Morsemanship.

Morse code was NEVER an intellectual achievemnt, NEVER a
'technology.' It was, is, and will remain, just a psycho-
motor skill acquired through hours of practice. It requires
an APTITUDE for the on-off patterns similar to drumbeat
rhythms. Some take a VERY long time to master it at slow
speeds while others can learn quickly to achieve high rates.

The OLD S25 of the ITU Radio Regulations had a political
flavor to it...that of mandating adminstrations to test for
morse code for licenses having "below 30 MHz privileges."
Now "30 MHz" is an arbitrary choice. It is the top of the
definition of the HF decade in the spectrum. The next-
higher amateur radio band begins at 50 MHz and distance
propagation isn't very good up there. The limit on 30 MHz
APPEASED the old-timers in ham radio who regarded the ham
HF bands as "theirs" and wanted to keep morse code in the
very worst way. The International Amateur Radio Union
saw the present-day realism and did not want to appease the
old-timers or give in to their morse mythos. S25 got an
almost total rewrite in 2003 to bring it up to relatively
modern times. [S25 hasn't quite reached this new millennium

yet but give it time...]

Now, as to ORIGINAL INNOVATIONS, I can think of only TWO and
both of those done by Brits: Peter Martinez for PSK31 and
Mike Gingell for his R-C Polyphase Network used in SSB
modulation-demodulation other than by more-expensive crystal
filters. Those were new, original. Mike Gingell did his
Polyphase network for a PhD in the UK before moving to USA.
Martinez used Gingell's network in a ham transceiver
application three decades ago and has continued to innovate
things in HF radio. All the rest are ADAPTATIONS of EXISTING
commercial applications in circuits and systems...some very
good but still ADAPTATIONS, not ground-breaking new things.

>How about if he does as much innovating as has N2EY, W3RV, K0HB, K8MN,
>and K4YZ.

W3RV, K8MN, and K4YZ will be LOST behind the front panel of
any radio having semiconductors. N2EY now builds KITS
using semiconductors...his last described tube rig was a
kluge of tube circuits made from the equivalent of dumpster
diving (minimal cost some kind of achievement). Hans
probably can go behind the front panel and understand things
since he remains working in true high-tech electronics (the
only questions there is his being a 'manager,' a postion
not always held has having real-savvy technical smarts by
those working in the electronics industry). :-)

>Hmmm? Did I leave Cecil off the list on purpose?

Cecil got tired of the self-righteous, self-important few
morsemen on RRAP and inhabited RRAA. Cecil likes to try
out antenna designs...and does some good things there from
what I've read elsewhere. Cecil has more patents awarded
than I...perhaps five (?) in all.

>> We will all be waiting Len.
>
>We? You are trolls?

They are...Steppin Wolfe and all the other anony-mousies
eager to do Word War III in here. :-)

FCC 06-178 will become LAW of the USA soon. Whatever follows
(insofar as amateur radio is concerned) will happen. The
"predictions" in here are just Guesses, suppositions based
on individual's mode biases. What will be will be...

Best regards,
LenAnderson@ieee.org

The Neobryllium-Reszonifier is also contain unobtanium. It's classified as
a monode device.

Chuck:

I have been tearing apart this place. About a year ago I had constructed one for 10 meters and had all my notes, etc. Now can't find a thing.

This link:
http://www.cebik.com/trans/gamma.html

will show you details of a gamma match. It is being used on a dipole element. Basically, you just use the top half of the element, the half with the gamma match. Just below the gamma match, you chuck in a 1:1 current balun to choke off the rf which might go to the outside of the coax.

A counterpoise of wire, cut to 1/2 wave at the center freq. of the band can be attached to the outside of the coax (or coax connector) at the antenna.

The monopole radiator is a simple 1/2 wave and the length can be computed from the standard formula: 5904/(frequency in mhz) = length.

The link above contains a basic program to compute the gamma match dimensions. You should be able to tear the formulas out of the text and use them manually.

I will see if I can't find the material on dimensions, etc. I had put together here, still looking.

Scott,

You can have simultaneous H & V polarization. FM broadcast antennas usually produce both, because they transmit to both home stations that use horizontal-polarized antennas, and automobiles that have vertical-polarized antennas. For an omni pattern, they'll have either two sets of elements (H+V), or a combined horizontal loop + vertical radiator. Dielectric Communications (http://www.dielectric.com/broadcast/fm.asp) offers the both types.

You are not asking for the moon. What you want is a simple, compact, reliable antenna for both 144 and 440 MHz.. Having done a fair amount of that sort of RACES/ARES stuff, here's what I'd advise you.

Go down to your local radio parts store, Rat Shack if that's all you've got and get yourself a female BNC chassis connector (UG-1094, RS # 278-105). Get a couple of quality male BNC cable connectors while you are at it. Unfortunately for you, RS doesn't sell anything but that twist-on solderless crap for male BNC, so you may wind up buying them mail order.

Get yourself four 3/8" solder lugs and five 19" pieces of solid #14 copper wire (strip house romex if you have to).

To each of the four solder lugs, solder one end of the #14 wire. These will be the four ground plane wires. THe fifth piece of #14 will connect to the solder cup on the bottom of the female BNC chassis connector to become the radiating element.

Now put those four solder lugs over the radiating element and over the threads on the connector. Use the nut that came with the connector to fasten the solder lugs, each at approximately 90° from each other (a small crescent wrench or dedicated 1/2" wrench needs to be part of your permanent tool kit). Bend them down at about a 45° angle.

Take the two male connectors and make an RG-58 cable to run from your radio to where you want to put your antenna. Connect one end of the cable to your radio and the other end to the UG-1094 connector.

You want to move the antenna? Disconnect the cable. Grab your wrench and pull that nut off. Take off all 4 ground plane wires. Bundle them up around the radiating element. Reassemble in the new location. Ten seconds up, ten seconds down.

You want to use it in the field outside? Bend a small hook (no more than 1/4" long) in the radiating element. Tie a roll of heavy twine to the hook and bend the hook shut. Take the roll of twine and throw it around the highest tree limb you can find. Hoist that sucker up and you are on the air.

We can dick around with a mounting bracket on the UG-1094 threads if you want to make a permanent installation out of it.

(By the way, you are operating close enough to the third harmonic of 144 on 440 that the antenna will perform quite well on both frequencies.)

Jim

I recall Cecil succumbing to their jeers to join them on CW. Poor bastard so wanted to prove himself to them that he operated CW with a thunderstorm overhead and lightning alqds. After such heroics, they still don't like his ideas and ostracize him.

Whatever would be the point of that?

Here are just *some* of yours, Brian Burke:

1577 as hot-ham-and-cheese@hotmail.com
2863 as burke1@icss.net
2973 as billybeeper@juno.com
2211 as brianburke@my-dejanews.com

These are just your posts to rrap, and just the ones using those four
screen names. There are probably many more under other names.

Total comes to 9,624.

Google never forgets.

There are probably other screen names

It will even perform well as a satellite antenna on
440. EZNEC says it has a TOA of about 45 degrees.

And I did not mean to imply that you couldn't use brazing (not welding) rod, which is nothing but brass and a little more to make the elements. IT certainly makes a STIFFER antenna, but copper wire is a lot easier to work with.

Hmmm. In some cases, would be nice to keep more of that signal terrestrial.

Len, Len, Len ...

There are many here whose time has come and gone. They have only their retirement check, SSI, time and antique radio gear.

You think anyone, but another one, can get along with any one of them?

That's why you bend the radials down at a 45. It bends the pattern right
along with it.

> Morse Code is in distress.
> ......
> ......
> While the decision had been expected, some ham radio operators fear that
> their

"""""""exclusive club"""""

I think this is the key to Ms Kotts reaction.
New folks "the unwashed masses" are going to move into what she thinks of as her exclusive neighborhood, and things will be different.
Change is upsetting, but change happens.
Deal with it.
Radio and Cw were "new fangled technology" in 1905, because she grew up with this technology, She wants to stick to the 19th century technology she is familiar with.
If the CDC did that, people would be dying like flies from what are NOW preventable diseases like Measles, Cholera, typhoid , typhus, Yellow Fever, etc.And surgery would be done without anaesthesia.

> - and that the very survival of Morse Code is in question.
NO this is not true! Once knowledge is discovered it willl not DIE. Its usage may decline as other technologies supplant it, BUT it will survive.

> ......
> The demise of the Morse requirement, however, could be a boon for ham
> radio itself. After the FCC decision, demand for information
> about radio licenses surged from about 200 in a typical weekend to about
> 500, according to the American Radio Relay League, an

A surge in interest is a GOOD thing. Too many Old Farts like me (age 55), and not enough youngsters coming in to the hobby.

> ......
> "It's part of the dumbing down of America," said Nancy Kott, editor of
> World Radio magazine and a field representative for the

> Centers for Disease of Control and Prevention in Metamora, Michigan

IS this an Official policy if the CDC? Is she its authorized spokesperson????
.
Last time I was there, the CDC headquarters were outside Atlanta, Georgia.

>"We live in a society today that wants something for nothing."
>

That's the subtle point I was trying to make. To keep
the TOA low, the antenna should not exceed 5/8 WL.
6/8 WL raises the TOA. That's not optimum for hitting
repeaters unless they are on very high, very close
mountains.

CW is my favorite mode and I enjoy 10 wpm QSO's.
GMC is my favorite pickup. Vanilla Bean is my
favorite ice cream. Texas is my favorite state.
I just don't believe in forcing my favorite mode
on anyone else any more than I believe in forcing
my favorite pickup, my favorite ice cream, and
my favorite state on anyone else. What is wrong
with live and let live?

4573. Discussion points on a long term Prognosis for AMATEUR RADIO

Newsgroup: rec.radio.amateur.antenna
Date: 2006-12-30 21:15:53 UTC
From: Dan <winstonsalemve@yahoo.com>
Message-ID: <en8hbj$i7m$1@news04.infoave.net>
Source record: 47244

Thesis ONE

I am an OLDER Amateur and the long term prognosis of AR worries me.
I am NOT having a temper tantrum about the FCC doing away with the CW testing requirement.

This is a major change, but I think major changes are needed.
Change is upsetting to some people, but things that don't change are DEAD.

What further changes are needed???
>>
>>>>>>>>>>>>>>>>>>>

Thesis TWO

--------AR has not kept up with changing technology-------------
In WWI and WWII CW was state of the art. NOT so today.
Today Having an EXTRA or a 25 wpm certificate does not give you a better insight into, or better operating technique in today's radio communications systems.
>>
>>>>>>>>>>>>>>>>>>>>.

Thesis Three
Any how, when I got into AR in the early 80's after a long period as a SWL and CBer, there were a lot of guys my age (relative youngsters, age 25-30) just coming into AR.
I am just not seeing youngsters coming in today.

THIS WORRIES ME.

What can be done to bring new young blood into AR?

>>

Thesis FOUR

I have spent most of my adult life dealing with VHF, UHF and now 800MHz trunking systems.
CW to me isn't bad, its just not germane to my day to day existence.

I am an amateur who likes fiddling with things.
Not so much operating, as asking questions like: can I take those VHF-LO whips that are already on those trucks cut hem down a little bit, and turn them into 5/8 wave antennae for the new VHF HI system? That sure would save a lot of work drilling and installing new antennae.

Computers are the thing now, and the RF parts of their communication systems
are what is important now in radio.
I don' think we should kill off or stop using CW or SSB, nor do I think we
should allow robot stations using various protocols to spread everywhere.
To paraphrase Ecclesiastes: To every emission type there is some spectrum, A
band for Cw, a band for SSB, a band for PSK-31, etc.

<<<<<<<<Moderation in all things, and emission types.>>>>>>>>>>>.

>>
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

Thesis FIVE

The recent FCC ruling on CW and the changes in various HF emissions
authorizations are part of what I see as a slow but continuous movement
toward an AR licensing system that will only have two licenses.
Class A will be what used to be EXTRA, Advanced, and General, who will be
allowed to use all authorized bandwidths, emissions and frequencies.
Class B will be Techs, Tech Plus, and the old Novices who will be restricted
to frequencies above 30 or 50 MHZ, and they will be appliance operators not
allowed to adjust or repair their equipment.

Take a look at CEPT 1 and CEPT 2.

I think this is going to happen no matter what AR licensees have to say
about it, because the FCC is just not interested in AR.
AR is just not on their radar screens because the commissioners are from the
DC chattering classes have little or no personal technical expertise.
AR just cannot compete with the hordes of lobbyists and lawyers from the
various Telecommunications interest groups like the CTIA, the FCC Bar, NAB,
BPL operators,ATT, the various baby bells etc.
NO lobbyists = NO clout at the FCC

What can AR do to have some say about further changes mandated at the FCC?
>>
>>
Thesis SIX

When I got interested in radio 35+ years ago, it seemed to me that there
were several (non exclusive) "types"
1) talkers "ragchewers"
2) international goodwillers " Hey I just talked to a guy in Paraguay"
3)fiddlers "hey what happens if I put an extra capacitor in this power
supply I just built"
4) public service guys " I wonder if I could be the Eastern net control of
the TCC tonight after I clear the Races net?"

It seems to me that the international goodwill types have all gone away to
the internet.
And the fiddlers are fiddling around less and less because modern day
equipment to too small and complicated to work on at home, so they've gone
off into programming or computer building.

It appears to me that AR radiolicensees are devolving into two groups:
VHF public service/talkers
and
A declining number of fiddlers.

Is this good for AR?

Len, you used to argue that ham radio would benefit if only the FCC would let the brilliant RF scientists, engineers and physicists, who only lacked the ability or desire to learn Morse code, to enter the service. You also used to argue that the code was a roadblock to younger people entering the hobby. On the surface, these seemed to be some pretty noble ideals upon which to take the high road. This is all on the record.

But now it becomes clear that, with the Morse requirement indeed no longer a low tech obstacle to these high potential contributors, the promises of these positive outcomes have been pretty much toned down...by about 100%. Maybe they will happen but probably (I'm sure you agree) things will pretty much stay the same, other than the rise of another marginal increase in the lid factor similar towhat we saw on 75m with the advent of the 5wpm generals.

Now you say it was all only for freedom of choice.

When did your flip turn into a flop? :-))

It's inaccurate. You did not interrogate Google correctly, and so the
number you gave is much lower than the actual number.

If you can't be accurate, why should anyone trust you?

> says the Top Ten listing is "wrong."

Nope.

I'm saying *you* are giving a number that is very inaccurate. 6,191 is
a lot less than 10,993.

> That's a NEW
> territory of criticsm for him! :-)

"Criticsm"?

> The WORST I can be accused of is being incomplete. :-)

In error is more like it.

> cribs license class totals from the AH0A website
> and implies they are "his" since he NEVER shows the origin

No, that is not correct.

The totals I post every two weeks do not come from AH0A.

I have posted my source here. You are either too lazy or too
incompetent to find it ;-)

Seeing your following post explaining the mixup in attributes,
I'll toss a thing or two in here in response... :-)

The on-air get-together of morsemen was reported in here in
some detail and Cecil really did do his thunderstorm thing.
Considering Cecil's method of antenna matching...open-wire
feedline stubs switched in by knife switches...it is one
heckuva dangerous exercise to peak his wire antenna response!

I admire Cecil Moore for his free-thinking ability...plus
his nifty Harley-Davidson motorcycle (called a "hog" among
motor afficionados). :-) He moved back to Texas to take
care of his ailing parents, something I had in common with
him and don't wish that on anyone.

Not all of the correspondents in here are in retirement!
Most of the adamant morsemen seem to be, though, but
Jimmie Noserve "is not." Since only a select few of his
"inner circle" of (morsemen) friends seem to know what
he does and where so "N2EY" isn't yet retired...but he
sounds like he is in his 80s or 90s, though.

The Prussian pedant ("K8MN") has his government pension
checks and as a retiree of the federal government it would
probably not be from the SS. He only ACTS like he was in
the SS. :-)

>You think anyone, but another one, can get along with any one of them?

I don't think a chronological contemporary can "get along" with them unless they are part of the wish-fulfillment tribe called morsemen. They are SET in their ways, unable to adapt, yet all want to be "leaders" or, at the very least, "respected" for their unfailing devotion to old, old standards and practices in a radio hobby.

Most won't acknowledge that amateur radio IS a hobby... those are off into their own wish-fulfillment dreams of honor, glory, majesty, and "service to their country" by having that particular hobby. Sheesh.

Now there's nothing at all wrong with having a fascinating hobby. Amateur radio IS a fascinating hobby. It can be fun, it can be a recreation. Some folk in here let it dominate their life and THAT gets them off into some fantasies of their own. Not a good thing. For them or the ones they are around. Especially so if their whole being in the hobby are dominated by a self-styled few leaders up in the NE USA. The STRICT ordering of jargon and protocol and 'We' do things 'differently' (as in the standards of over a half century ago) gets a bit annoying to technology liberals. Radio itself is only 110 years old and is constantly changing. To be stuck in the beginning middle of that technology lifespan (never to change) seems an absurd ultra-conservative fixation with old technology.

It's worse with the fixation towards on-off keyed CW. Morse code was first used in 1844...BEFORE radio existed as a communications medium. Why in hell a 162-year-old mode "must" be a "qualifier" for an amateur radio license is ludicrous. That "need" to preserve a truly archaic mode HAS to be the result of intense mental conditioning (commonly called brainwashing) by the you-know-who organization (the main 'news' source for USA amateur radio).

On the other hand, the strict adherence to standards and protocol of olden times MAY be satisfactory for all those who have difficulty with adaptation to newer technology. That adherence can be a comfort, a psychological survival factor perhaps, but it doesn't alleviate their inability to adapt. Trying to get everyone else to conform to THEIR beloved adherence to old standards and practices is very, very wrong and also very selfish of them.

Nope, I think I had one with my call. I switched to an "anon" after too much unwarranted attention was being paid to where my residence was by some of the bad elements on RRAP. Then Hans asked me to give up Billy, and I did. I selected a screen name with "ham" in the title just for fun.

Now, Jim, would you mind tallying up all of your postings under all of your screen names?

Betcha can't.

Dear John in UK (no call sign):

Five bands (14, 18, 21, 24, 29 MHz?) with one transmission line shouts
for the use of a LDPA. You can construct one that will work using
information in the ARRL Antenna Book or several other references.

Prof. Cebik has a number of notes on this type of antenna
(www.cebik.com). A good place to start is:
http://www.cebik.com/lpda/lpd.html

A Michigan company that I understand has dealers in UK, is Tennadyne.
http://www.tennadyne.com/index.html
They make good quality, simple LPDAs. I have no connection to the firm.

Successfully nesting five tightly coupled antennas is a very difficult
task. A LPDA will work.

73 Mac N8TT

I like the one where he goes on and on and on about Amateur
contributions during WWII, when everyone know that the gubmn't shut
down amateur radio during WWII. None-the-Less, he goes on and on and
on about it.

A full wave 20 meter delta loop, fed with open wire, ladder line or
even TV twin lead & a tuner will load up on all bands 10-40 meters.

Performance on 10-20 will be good, 30 & 40 a little less so.

All this stuff about dumbing down America is garbage. This lady works
for the CDC and has this kind of attitude? Thats scary. By the same
token, I guess a physician is less of a doctor, is 'dumb' because he
uses an MRI to make a diagnosis rather than cutting someone open for
exploratory surgery.
Telegraphy (in its simplest form, smoke signals) has been around
for thousands of years, keys for a bit over 200. Its time to move on
people.
CW is a nice skill to have, as are woodworking, horseback riding
and knitting. But not one of them is relevant to life in the 21st
century. not even a little bit. If everyone with those abilities fell
off the planet right now, the world would hardly notice the loss. Thats
just the way it is. Amatuer Radio operators can be innovators that
move along with the times and embrace new opportunities (as we have
done for the most part) or we can keep crying about how things were in
the good old days and become (extinct) dinosaurs.
Now if you will excuse me I need to start studying for my General.

I agree -- Chuck isn't looking to work big DX so, a complicated antenna is not needed. Another simple concept is a vertical dipole. Here's an illustration from "Simple, Low Cost Wire Antennas for Radio Amateurs", by William I. Orr and Stuart D. Cowan: http://tinyurl.com/yzydbo
The bottom section connects to the shield of the feedline. If made from tubing, it will act to decouple the outer surface of the shield. If cut for 144-148MHz (38-39" overall length), it will work at 432-444MHz as well. To make it portable, use stiff wire (welding rod, etc) for the top half, and schedule-40 ⁄" copper tubing for the bottom half. An insulated coupling can be fashioned from wood or plastic dowel or plastic pipe. More dowel or plastic pipe can be used as a carring handle. Like the ground plane, it can be suspended from an overhead support. It can also be slipped into/onto a baseplate if you don't have an overhead support available: nonmetallic umbrella stand, heavy flower vase, etc. With the exception of the feedline, your home improvement box store will have all the parts you need.

You remind me. I have built those antennas, long ago, in the past for 10M+ bands.

If I remember correctly they were termed "bazooka antennas." I kind of remember there was a recommended ratio of coax shield dia. to inside diameter of the sleeve--possibly the ratio of the radiating element figured into securing a 50/75 ohm match also?

You have any more data on that antenna?

Warmest regards,
JS

Thanks. I appreciate the suggestion, but I have built the antenna you described, using welding rod, plus a 440 MHz (smaller version), but in a crowded room the radials stick out farther than I want. I tried building a TV antenna line J-Pole today, but the SWR was higher than I expected. I haven't tried shortening it yet, but will when I get time. But I would still have to find some way to hang it from the ceiling or something. I really want something small, unobtrusive and cheap and easy to build.

Hi John,

I found the image here: http://www.alpharubicon.com/elect/vertdipoleniet.htm and cleaned it up. There're more links to bazooka antennas here: http://www.dxzone.com/catalog/Antennas/Bazooka/ I thought this construction method: http://www.start.ca/users/ldblake/bazooka.htm was particularly innovative.

Hi Chuck,

I found the image here: http://www.alpharubicon.com/elect/vertdipoleniet.htm and cleaned it up -- not much more info available on that page. It's basically a dipole turned vertical. With the feedline going thru the bottom half and connecting at the top of that section, it becomes a "bazooka" vertical.

There're more links to bazooka antennas here: http://www.dxzone.com/catalog/Antennas/Bazooka/ I thought this construction method: http://www.start.ca/users/ldblake/bazooka.htm was particularly innovative. I don't think you'd need to use RG-8 as described -- just about any 50-ohm feedline would work fine.

Good one Dave. When you start "studying" for your general you will see how dumbed down and simple it is and you might marvel at why the QPC would have ever even bothered to commit such a "test" to publication. It may also occur to you that, as the the Geico commercial says, it is so easy a caveman could do it. Actually I would move back perhaps 25 millions earlier in the evolutionary cycle and say it is so easy, even a monkey could do it.

And monkeys it will be.

The new Monkey General class :-)

I'm sure you know what you want, and I'm sure you have all the lab equipment
necessary to calculate VSWR on an antenna inside a conductive structure.
I'm also sure you have built antennas for emergency and portable use for
fifty years, so you are on your own so far as I'm concerned.

Cheap, easy, small. Pick two.

Best of luck; write if you get work.

Jim

For years now I have had an alarm on the wall of the shack; its' meter needle has never moved.

I built it for an old-old magazine article issued on April 1 of some past year, written by a Dr. Kuku I believe.

I surely thought I must have made an error in its' construction, as, like I say, the meter needle has NEVER moved.

But, darn it, when I opened up your post--the damn meter needle went clear off scale!

Darn ku-ku meter works!!!

Jim:

Alright, it's not a bazooka; it's a decoupling sleeve (thank you for the enlightenment). Semantics aside, it will do what the OP wishes it to, and in a physical representation that will work within his constraints.

Yup, the peak of the main lobe is elevated. ... but my 144 copper pipe j-pole does put sufficient 440 energy toward the horizon that I am often able to hit a repeater more than 70 miles away (Santiago Peak in Orange County CA from southern San Diego County). Power out is around 4 watts from a Yaesu FT-530.

Just now I tried Santiago and didn't hear back, so I tried 449.08 on Palomar Mountain, 45 miles away, with a half watt and bought it up. Antenna is only 20 ft above ground; house is around 510 ft above sea level on a small rise.

Yes you should be able to build one out of welding rod. I built mine out of brazing rod and an N connector. It is an open stub design where the bottom end of the matching section is open instead of shorted like most designs and is fed from the bottom. 3/4 wl part is connected directly to the center pin of an N connecter, short side is connected to the outside of the N connector. Seems to work OK but it got to be a real pain and probably a saftey hazard "put your eye out kid". Finally made an in-door antenna modeled after a 60s 70s style pole lamp. SImplest version was a piece of PVC pipe about 8 ft long that you wedge between ceiling anf floor and tape a dipole to the antenna. I think I still have a wooden one around somewhere that uses pieces of a tape measure for elements..

EZNEC says the feedpoint of a 20m loop will be about
3000-j13000 on 40m. The SWR on the ladder-line line
will be around 130:1. For better performance on 40m,
install an insulator opposite the feedpoint thus
turning it into a dipole of sorts on 40m. Short across
the insulator for 20m operation.

Yep, paraphrasing Roy:
All antennas emit energy at all angles.

I just don't like to waste 10m/VHF/UHF energy
at high angles.

this is the best reasoned and fully thought through forecast of what is
likely to happen to AR in north america/uk/europe in the next 5---20
years.All of us involved in the HOBBYmust get our acts TOGETHER in order to
retain as many aspects of our wonderful pasttime in the face of the greed
of governments and "bottom line" greed.however I am very discouraged by the
amount of anger agressiveness rage and obscenity posted to this and other
subject related Newsgroups.
and fyi I am 80 years old and am learning pc skills from my 14 year old
grandson and his 12 year old sister--so there is always something else to
learn as technology advances(how can we use it to expand/improve the hobby
"??? .just a few not so rambling thoughts. happy new year to all from

Happy New Year

I am trying mobile operations for the first time...FT8900 Quad band XCVR and Diamond CR8900 quad band antenna (10, 6, 2M and 440Mhz). I am mounting the antenna on the hatchback of an Element.

I am wondering how significant is the proximity of the AM antenna (a stubby affair presumably housing some sort of coil?) to the new ham antenna. I can mount the antenna on the driver's side of the hatchback or the passenger side. The passenger side is within a foot or two of the AM stub antenna.

I would think in either case the AM antenna is in the Near Field.
Will the antenna pattern be significantly more affected on the passenger side?

Thanks in advance for all helpful replies ;)

Happy New Year John,

Then it is best to resign yourself to the inevitable. Yes both will
be in the other's near field.

It isn't going to matter all that much unless the AM antenna becomes
resonant on one of those bands you use. Even then, it will only
matter in terms of match as the parasitic element is going to pull the
source. Unless it means punching holes in sheet metal, you can try
all possible sites and check SWR.

As for patterns, again the parasitic element (the AM antenna) will
have to support substantial currents (through coupling and matching -
and hence a significant SWR hit) to disturb the pattern. More likely
is that the sheet metal of the car and the site location of the
transmitting antenna is going to be of a far greater determiner of
pattern shape.

Cecil:

And, neither do I. (well, 11m band--sometimes. Just for medicinal purposes, mind you. <evil grin>)

I have pursued the "Ultimate 10M Antenna", and a yaga or quad is/are great. However, I like a omni to listen for traffic on. And, when there are high winds, I like to point those directional antennas into the wind. (have stripped too many rotor gears and suffered too much damage in past decades)

Like you point out, and I concur, the perfect Omni which throws no rf to the sky is elusive ... strange too, we can do it with light.

I have gotten used to the "RF GODS" extracting their portion of my rf field to their realms in the sky :((sometimes they toss a bit back to australia though, I like the women there :))

Regards,
JS

Hi John,

Thank you for your reply-I'm pleased that you liked my article on the FCC in WW2.
I apologize for the delay in responding, but I have been overwhelmed by the number of responses, and the time consumed with house guests over the Holidays that prevented me from getting to the keyboard in a timely manner.
I submitted another article to QST, but they said there was insufficient space for it, so they published it on the ARRL Web Extra page. That page has not been well publicized, so only a few have seen it. I believe you will also find this article interesting, and the easiest way to see it is to go to Google and enter 'Evolution of K2BSA'. It is the story of how the National Headquarters of Boy Scouts originally acquired an amateur radio station.
You might also find my own web page of interest. I invite you to take a look at www.w2du.com.
73, and a Happy New Year!
Walt, W2DU

Another mounting option may be to use the location for the roof rack. Look for the rectangular plastic parts above the driver's door. They pop out and under some you will find the mount for the roof rack. This would get you 3-4 feet from the AM/FM antenna.

The stubby antenna is probably active so it may not appreciate high signal levels.

hi

don't want to talk you out of the jpole but have you seen the

Moxon for 2m ? Direct fed with 50 ohm coax.

http://www.cebik.com/moxon/moxbld.html

has gain similar to a 2 element yagi but takes up less space,
and no radials to worry about.
